2009/07/01

Abstract

`ntheorem.sty` is a package for handling theorem-like environments. Aditionally to several features for defining the layout of theorem-like environments which can be regarded to be standard requirements for a theorem-package, it provides solutions for two related problems: placement of endmarks and generation of lists of theorem-like environments.

In contrast to former approaches, it solves the problem of setting endmarks of theorem-like environments (theorems, definitions, examples, and proofs) *automatically* at the right positions, even if the environment ends with a `displaymath` or (even nested) list environments, it also copes with the `amsmath` package. This is done in the same manner as the handling of labels by using the `.aux` file.

It also introduces the generation of lists of theorem-like environments in the same manner as `listoffigures`. Additionally, more comfortable referencing is supported.

After running LaTeX several times (depending on the complexity of references, in general, three runs are sufficient), the endmarks are set correctly, and theoremlists are generated.

Since `ntheorem.sty` uses the standard LaTeX `\newtheorem` command, existing documents can be switched to `ntheorem.sty` without having to change the `.tex` file. Also, it is compatible with LaTeX files using `theorem.sty` written by Frank Mittelbach.

Contents

1   Introduction

For our purposes here, "theorems" are labelled enunciations, often set off from the main text by extra space and a font change. Theorems, corollaries, conjectures, definitions, examples, remarks, and proofs are all instances of "theorems". The "header" of these structures is composed of the type of the structure (such as THEOREM or REMARK), a number which serializes the instances of the same type throughout the document, and an optional name (such as "Correctness Theorem"). The layout of theorems can be changed by parameters as the fonts of the header and the body, the way how to arrange the headers, the indentation, and the way of numbering it. Confronted with these requirements, `theorem.sty`, a style for dealing with theorem layout was developed by Frank Mittelbach which was the standard theorem-environment for long time.

But then the desire for additional features like "endmarks" and "theorem-lists" arose. Two extensions of `theorem.sty` were developped: One for handling endmarks, `thmmarks.sty` and one for generating lists, `newthm.sty`. Thus, Frank Mittelbach suggested to combine the new features into one "standard-to-be" package. And now, here it is.

2   The User-Interface

2.1   How to include the package

The package `ntheorem.sty` is included by

    `\usepackage[`⟨*options*⟩`]{ntheorem}`,

where the optional parameter ⟨*options*⟩ selects predefined configurations and special requirements.

The following ⟨*options*⟩ are available by now, concerning partially independent issues:

Predefined environments: (see Section 2.3.6) With [standard] and [noconfig], it can be chosen, if and what file is used for activating a (user-defined) standard set of theorem environments.

Fancy boxes around theorems: The [framed] option allows to use `framed.sty` that provides boxes even across pagebreaks.

Activation of endmarks: [thmmarks] enables the automatic placement of endmarks (see 2.3); when using the `amsmath`-package, [thmmarks] must be complemented by [amsmath] (see Section 3.2).

Activation of extended reference features: [thref] enables the extended reference features (see Section 4.1); when using the `amsmath`-package, [thref] must be complemented by [amsmath] (see Section 3.2).

Compatibility with amsthm: option [amsthm] provides compatibility with the theorem-layout commands of the `amsthm`-package (see Section 3.2).

Compatibility with hyperref: option [hyperref] provides compability with the `hyperref`-package (see section 3.4).

2.2   Defining New Theorem Sets

\newtheorem   The syntax and semantics is exactly the same as in standard LaTeX: the command `\newtheorem` defines a new "theorem set" or "theorem-like structure". Two required arguments name the new environment set and give the text to be typeset with each instance of the new "set", while an optional argument determines how the "set" is enumerated:

`\newtheorem{foo}{bar}` The theorem set `foo` (whose name is `bar`) uses its own counter.

`\newtheorem{foo2}[foo]{bar2}` The theorem set `foo2` (printed name `bar2`) uses the same counter as the theorem set `foo`.

`\newtheorem{foo3}{bar}[section]` The theorem set `foo3` (printed name `bar`) is enumerated within the counter `section`, i.e. with every new `\section` the enumeration begins again with 1, and the enumeration is composed from the section-number and the theorem counter itself.

For every environment ⟨*name*⟩ defined by `\newtheorem`, *two* enviroments ⟨*name*⟩ and ⟨*name**⟩ are defined. In the main document, they have exactly the same effect, but the latter causes no entry in the respective list of theorems (cf. `\section` and `\section*`), see also Section 2.4.

\renewtheorem   Theorem sets can be redefined by `\renewtheorem`, with the same arguments as explained for `\newtheorem`. When redefining a theorem set, the counter is not re-initialized.

4

2.3 Defining the Layout of Theorem Sets

For theorem-like environments, the user can set parameters by setting several switches and then calling \newtheorem. The layout of a theorem set is defined with the values of the switches at the time \newtheorem is called.

2.3.1 Common Parameters for all Theorem Sets

\theorempreskipamount
\theorempostskipamount

These additional parameters affect the vertical space around theorem environments: \theorempreskipamount and \theorempostskipamount define, respectively, the spacing before and after such an environment. These parameters apply for all theorem sets and can be manipulated with the ordinary length macros. They are rubber lengths, ('skips'), and therefore can contain plus and minus parts.

2.3.2 Parameters for Individual Sets

The layout of individual theorem sets can be further determined by switches controlling the appearance of the headers and the header-body-layout:

\theoremstyle
- \theoremstyle{⟨style⟩}: The general structure of the theorem layout is defined via its \theoremstyle. \ntheorem provides several predefined styles including those of Frank Mittelbach's theorem.sty (cf. Section 2.3.4. Additional styles can be defined by \newtheoremstyle (cf. Section2.5.1).

\theoremheaderfont
- \theoremheaderfont{⟨fontcmds⟩}: The theorem header is set in the font specified by ⟨fontcmds⟩.

  In contrast to theorem.sty, \theoremheaderfont can be set individually for each environment type.

\theorembodyfont
- \theorembodyfont{⟨fontcmds⟩}: The theorem body is set in the font specified by ⟨fontcmds⟩.

\theoremseparator
- \theoremseparator{⟨thing⟩}: ⟨thing⟩ separates the header from the body of the theorem-environment. E.g., ⟨thing⟩ can be ":" or ".".

\theoremprework
- \theoremprework{⟨thing⟩}: ⟨thing⟩ is performed before starting the theorem structure. E.g., ⟨thing⟩ can be \hrule.

\theorempostwork
- \theorempostwork{⟨thing⟩}: ⟨thing⟩ is performed after finishing the theorem structure. E.g., ⟨thing⟩ can be \hrule.

\theoremindent
- \theoremindent{⟨dimen⟩} can be used to indent the theorem wrt. the surrounding text.

  ! It's a '(dimen)', so the user shouldn't try to specify a plus or minus part, because this leads to an error.

\theoremnumbering
- \theoremnumbering{⟨style⟩} specifies the appearance of the numbering of the theorem set. Possible ⟨styles⟩ are arabic (default), alph, Alph, roman, Roman, greek, Greek, and fnsymbol.

  Clearly, if a theorem-environment uses the counter of another environment type, also the numbering style of that environment is used.

<div style="margin-left:2em">

\theoremsymbol   • \theoremsymbol{⟨*thing*⟩}: This is only active if `ntheorem.sty` is loaded with option [`thmmarks`]. ⟨*thing*⟩ is set as an endmark at the end of every instance of the environment. If no symbol should appear, say \theoremsymbol{}.

The flexibility provided by these command should relieve the users from the ugly hacking in \newtheorem to fit most of the requirements stated by publishers or supervisors.

\theoremclass   With the command \theoremclass{⟨*theorem-type*⟩} (where ⟨*theorem-type*⟩ must be an already defined theorem type), these parameters can be set to the values which were used when \newtheorem was called for ⟨*theorem-type*⟩.
With \theoremclass{LaTeX}, the standard LaTeX layout can be chosen.

2.3.3 Font Selection

From the document structuring point of view, theorem environments are regarded as special parts inside a document. Furthermore, the theorem header is only a distinguished part of a theorem environment. Thus, \theoremheaderfont inherits characteristics of \theorembodyfont which also inherits in characteristics of the font of the surrounding environment. Thus, if for example \theorembodyfont is \itshape and \theoremheaderfont is \bfseries the font selected for the header will have the characteristics 'bold extended italic'. If this is not desired, the corresponding property has to be explicitly overwritten in \theoremheaderfont, e.g. by \theoremheaderfont{\normalfont\bfseries}

2.3.4 Predefined theorem styles

The following theorem styles are predefined, covering those from `theorem.sty`:

`plain`	This theorem style emulates the original LaTeX definition, except that additionally the parameters \theorem...skipamount are used.
`break`	In this style, the theorem header is followed by a line break.
`change`	Header number and text are interchanged, without a line break.
`changebreak`	Like `change`, but with a line break after the header.
`margin`	The number is set in the left margin, without a line break.
`marginbreak`	Like `margin`, but with a line break after the header.
`nonumberplain`	Like `plain`, without number (e.g. for proofs).
`nonumberbreak`	Like `break`, without number.
`empty`	No number, no name. Only the optional argument is typeset.

2.3.5 Default Setting

If no option is given, i.e. `ntheorem.sty` is loaded by \usepackage{ntheorem.sty}, the following default is set up:

</div>

```
\theoremstyle{plain},
\theoremheaderfont{\normalfont\bfseries} and
\theorembodyfont{\itshape},
\theoremseparator{},
\theoremindent0cm,
\theoremnumbering{arabic},
\theoremsymbol{}.
```

Thus, by only saying `\newtheorem{...}{...}`, the user gets the same layout as in standard LaTeX.

2.3.6 A Standard Set of Theorems

A standard configuration of theorem sets is provided within the file `ntheorem.std`, which will be included by the option `[standard]`. It uses the `amssymb` and `latexsym` (automatically loaded) packages and defines the following sets:

Theorems: `Theorem`, `Lemma`, `Proposition`, `Corollary`, `Satz`, `Korollar`,

Definitions: `Definition`,

Examples: `Example`, `Beispiel`,

Remarks: `Anmerkung`, `Bemerkung`, `Remark`,

Proofs: `Proof` and `Beweis`.

These theorem sets seem to be the most frequently used environments in english and german documents.
The layout is defined to be theoremstyle `plain`, bodyfont `\itshape`, Headerfont `\bfseries`, and endmark (theoremsymbol) `\ensuremath{_\Box}` for all theorem-like environments[1]. For the definition-, remark- and example-like sets, the above setting is used, except bodyfont `\upshape`. The proof-like sets are handled a bit differently. There, the layout is defined as theoremstyle `nonumberplain`, bodyfont `\upshape`, headerfont `\scshape` and endmark `\ensuremath{_\blacksquare}`. For a more detailed information look at `ntheorem.std` or at the code-section.

2.3.7 Framed and Boxed Theorems

With the advent of the `framed` package (by Donald Arseneau) in 2001, a feature that has often been asked for for ntheorem could be implemented: theorems that are framed, or that are put into a colored box. It requires to load the `framed` package; shaded theorems also require the `pstricks` package. Frames and colored boxes are orthogonal to the existing theoremstyles – thus, they can be combined in arbitrary ways.

`\newframedtheorem` A theorem type can be framed by defining it by

`\newframedtheorem{...}{...}`

with the same parameters as usually for `\newtheorem`. Note that the use of the `framed` package also allows to have longer theorems across a page break framed.

`\newshadedtheorem`

The same ideas hold for theorems in shaded boxes. The declaration

---

[1]Note, that mathmode is ensured for the symbol.

```
\newshadedtheorem{...}{...}
```

declares a theorem environment that is shaded. By default, the background color is `gray`. This can be changed by defining

```
\shadecolor{⟨color⟩}
```

before declaring the theorem type. Note that later declarations of other shaded theorem types can use another shadecolor.

By default, the box is given as a `\psframebox` (see `pstricks` package) with shadecolor as `linecolor` and `fillcolor`. All these parameters can be changed by setting

```
\def\theoremframecommand{⟨any box command⟩}
```

before declaring the theorem type (for examples, the user is referred to section 4).

2.3.8 Customization and Local Settings

Since the user should not change `ntheorem.std`, we've added the possibility to use an own configuration-file. If one places the file `ntheorem.cfg` in the path searched by TeX, this file is read automatically (if `[standard]` is not given). The usage of `ntheorem.cfg` can be prevented by the `[noconfig]` option. Thus, just a copy of `ntheorem.std` to `ntheorem.cfg` must be made which then can freely be modified by the user. Note, that if a configuration-file exists, this will always be used (I.e. with option `standard` and an existing configuration-file, the `.cfg` file will be used and the `.std` file won't.

2.4 Generating Theoremlists

\listtheorems   Similar to the LaTeX command `\listoffigures`, any theorem set defined with a `\newtheorem` statement may be listed at any place in your document by

```
\listtheorems{⟨list⟩}
```

The argument ⟨*list*⟩ is a comma-separated list of the theorem sets to be listed. For a theorem set ⟨*name*⟩, only the instances are listed which are instantiated by `\begin{⟨name⟩}`. Those instantiated by `\begin{⟨name⟩*}` are omitted (cf. `\section` and `\section*`).

For example, `\listtheorems{Corollary,Lemma}` leads to a list of all instances of one of the theorem sets "Corollary" or "Lemma". Note, that the set name given to the command is the first argument which is specified by `\newtheorem` which is also the one to be used in `\begin{theorem} ... \end{theorem}`.

If `\listtheorems` is called for a set name which is not defined via `\newtheorem`, the user is informed that a list is generated, but there will be no typeset output at all.

2.4.1 Defining the List Layout

\theoremlisttype   Theoremlists can be formatted in different ways. Analogous to theorem layout, there are several predefined types which can be selected by

```
\theoremlisttype{⟨type⟩}
```

The following four ⟨*type*⟩s are available (for examples, the user is referred to section 4).

all   List any theorem of the specified set by number, (optional) name and pagenumber. This one is also the default value.

allname Like all, additionally with leading theoremname.

opt   Analogous to all, but only the theorems which have an optional name are listed.

optname Like opt, with leading theoremname.

2.4.2 Writing Extra Stuff to the Theorem File

Similar to \addcontentsline and \addtocontents, additional entries to theoremlists are supported. Since entries to theoremlists are a bit more intricate than entries to the lists maintained by standard LaTeX \addcontentsline and \addtocontents cannot be used in a straightforward way[2].

\addtheoremline   Analogous to \addcontentsline, an extra entry for a theorem list can be made by

$$\addtheoremline\{\langle name\rangle\}\{\langle text\rangle\}$$

where ⟨*name*⟩ is the name of a valid theorem set and ⟨*text*⟩ is the text, which should appear in the list. For example,

\addtheoremline{Example}{Extra Entry with number}

generates an entry with the following characteristics:

- The Label of the theorem "Example" is used.
- The current value of the counter for "Example" is used
- The current pagenumber is used.
- The specified text is the optional text for the theorem.

Thus, the above command has the same effect as it would be for

\begin{Example}[Extra Entry with number] \end{Example}

except, that there would be no output of the theorem, and the counter isn't advanced.

\addtheoremline*   Alternatively you can use

\addtheoremline*{Example}{Extra Entry}

which is the same as above, except that the entry appears without number.

\addtotheoremfile   Sometimes, e.g. for long lists, special control sequences (e.g. a pagebreak) or additional text should be inserted into a list. This is done by

\addtotheoremfile[⟨*name*⟩]{⟨*text*⟩}

where ⟨*name*⟩ is the name of a theorem set and ⟨*text*⟩ is the text to be written into the theorem file. If the optional argument ⟨*name*⟩ is omitted, the given text is inserted in every list, otherwise it is only inserted for the given theorem set.

---

[2]for a theorem, its number has to be stored explicitly since different theorem sets can use the same counter. Also, it is optional to reset the counter for each section.

2.5 For Experts: Defining Layout Styles

2.5.1 Defining New Theorem Layouts

\newtheoremstyle   Additional layout styles for theorems can be defined by

$$\texttt{\textbackslash newtheoremstyle}\{\langle name\rangle\}\{\langle head\rangle\}\{\langle opt\text{-}head\rangle\}.$$

After this, \theoremstyle{⟨name⟩} is a valid \theoremstyle. Here, ⟨head⟩ has to be a statement using two arguments, ##1, containing the keyword, and ##2, containing the number. ⟨opt-head⟩ has to be a statement using three arguments where the additional argument ##3 contains the optional parameter.

Since LaTeX implements theorem-like environments by \trivlists, both header declarations must be of the form \item[... \theorem@headerfont ...]..., where the dotted parts can be formulated by the user. If there are some statements producing output after the \item[...], you have to care about implicit spaces.

Because of the @, if \newtheoremstyle is used in a .tex file, it has to be put between \makeatletter and \makeatother.

For details, look at the code documentation or the definitions of the predefined theoremstyles.

\renewtheoremstyle   Theorem styles can be redefined by \renewtheoremstyle, with the same arguments as explained for \newtheoremstyle.

2.5.2 Defining New Theorem List Layouts

\newtheoremlisttype   Analogous, additional layouts for theorem lists can be defined by

$$\texttt{\textbackslash newtheoremlisttype}\{\langle name\rangle\}\{\langle start\rangle\}\{\langle line\rangle\ \}\{\langle end\rangle\}.$$

The first argument, ⟨name⟩, is the name of the listtype, which can the be used as a valid \theoremlisttype. ⟨start⟩ is the sequence of commands to be executed at the very beginning of the list. Corresponding, ⟨end⟩ will be executed at the end of the list. These two are set to do nothing in the standard-types. ⟨line⟩ is the part to be called for every entry of the list. It has to be a statement using four arguments: ##1 will be replaced with the name of the theorem, ##2 with the number, ##3 with the theorem's optional text and ##4 with the pagenumber.

WARNING: Self-defined Layouts will break with the hyperref-package.

\renewtheoremlisttype   Theorem list types can be redefined by \renewtheoremlisttype, with the same arguments as explained for \newtheoremlisttype.

2.6 Setting End Marks

The automatic placement of endmarks is activated by calling ntheorem.sty with the option [thmmarks]. Since then, the endmarks are set automatically, there are only a few commands for dealing with very special situations.

\qed
\qedsymbol   If in a single environment, the user wants to replace the standard endmark by some other, this can be done by saying \qed, if \qedsymbol has been defined by \qedsymbol{⟨something⟩} (in option standard, \qedsymbol is defined to be the symbol used for proofs, since a potential use of this features is to close trivial corollaries without explicitly proving them).

Additionally, if in a single environment of a theorem set, that is defined without an endmark, the user wants to set an endmark, this is done with `\qedsymbol` and `\qed` as described above. `\qedsymbol` can be redefined everywhere in the document.

`\NoEndMark`
`\TheoremSymbol`
On the other hand, if in some situation, the user decides to set the endmark manually (e.g. inside a figure or a minipage), the automatic handling can be turned off by `\NoEndMark` for the current environment. Then – assumed that he current environment is of type ⟨*name*⟩, the endmark can manually be set by just saying `\`⟨*name*⟩`Symbol`.

Note that there must be no empty line in the input before the `\end{theorem}`, since then, the end mark is ignored (cf. Theorem 3 in Section 4).

2.7   Extended Referencing Features

The extended referencing features are activated by calling `ntheorem.sty` with the option `[thref]`.

Often, when writing a paper, one changes propositions into theorems, theorems into corollaries, lemmata into remarks an so on. Then, it is necessary to adjust also the references, i.e., from "`see Proposition~\ref{completeness}`" to "`see Theorem~\ref{completeness}`". For relieving the user from this burden, the type of the respective labeled entities can be associated with the label itself:

   `\label{`⟨*label*⟩`}[`⟨*type*⟩`]`

associates the type ⟨*type*⟩ with ⟨*label*⟩.

This task is automated for theorem-like environments:

   `\begin{Theorem}[`⟨*name*⟩`]\label{`⟨*label*⟩`}`

is equivalent to

   `\begin{Theorem}[`⟨*name*⟩`]\label{`⟨*label*⟩`}[Theorem]`

`\thref`
The additional information is used by

   `\thref{`⟨*label*⟩`}`

which outputs the respective environment-type *and* the number, e.g., "Theorem 42". Note that LaTeX has to be run twice after changing labels (similar to getting references OK; in the intermediate run, warnings about undefined reference types can occur).

The `[thref]` option interferes with the `babel` package, thus in this case, `ntheorem` has to be loaded *after* `babel`. It also interferes with `amsmath`; see Section 3.2.

2.8   Miscellaneous

Inside a theorem-like environment ⟨*env*⟩, the name given as optional argument is accessible by `\`⟨*env*⟩`name`.

3 Possible Interferences

Since `ntheorem` reimplements the handling of theorem-environments completely, it is incompatible with every package also concerning those macros.

Additionally, the `thmmarks` algorithm for placing endmarks requires modifications of several environments (cf. Section 7). Thus, environments which are reimplemented or additionally defined by document options or styles are not covered by the endmark algorithm of `ntheorem.sty`.

The `[thref]` option changes the `\label` command and the treatment of labels when reading the `.aux` file. Thus it is potentially incompatible with all packages also changing `\label` (or `\newlabel`). Compatibility with babel's `\newlabel` isa achieved if babel is loaded before ntheorem.

3.1 Interfering Document Options.

`ntheorem.sty` also copes with the usual document options `leqno` and `fleqn`[3]. If one of those options is used in the `\documentclass` declaration, it is automatically recognized by the `thmmarks` part of `ntheorem.sty`.

If one of those options is not used in `\documentclass`, but with `amsmath` (see next section), it must not be specified for `ntheorem`, since all `amsmath` environments detect this option by themselves.

3.2 Combination with amslatex.

`ntheorem.sty` interferes with `amsmath.sty` and `amsthm.sty`.

Note, that the LaTeX amstex package `amstex.sty` (LaTeX2.09) is obsolete and you should use `amsmath` and `amstext` for LaTeX 2_ε instead. Up to `ntheorem-1.18`, it is compatible with `amsmath-1.x`. Since `ntheorem-1.19`, it is (hopefully) compatible with `amsmath-2.x`.

We would be happy if someone knowing and using `amsmath` would join the development and maintenance of this style.

3.2.1 amsmath

Compatibility with amsmath (end marks for math environments, and handling of labels in math environments) is provided in the option `[amsmath]`, (i.e., if `\usepackage{amsmath}` is used then

- `\usepackage[thmmarks]{ntheorem}` must be completed to `\usepackage[amsmath,thmmarks]{ntheorem})`, and also

- `\usepackage[thref]{ntheorem}` must be completed to `\usepackage[amsmath,thref]{ntheorem})`.

Note, that `amsmath` has to be loaded *before* `ntheorem` since the definitions have to be overwritten.

---

[3]although for `fleqn` and long formulas reaching to the right margin, equation numbers and endmarks can be smashed over the formula since `fleqn` does not use `\eqno` for controlling the setting of the equation number.

3.2.2 amsthm

`amsthm.sty` conflicts with the definition of theorem layouts in `theorem.sty`, some features of `amsthm.sty` have been incorporated into option [`amsthm`] which has to be used *instead of* `\usepackage{amsthm}`.

The Option provides theoremstyles `plain`, `definition`, and `remark`, and a `proof` environment as in `amsthm.sty`.

The `\newtheorem*` command is defined even without this option. Note that `\newtheorem*` always switches to the nonnumbered version of the current theoremstyle which thus must be defined.

The command `\newtheoremstyle` is not taken over from `amsthm.sty`. Also, `\swapnumbers` is not implemented. Here, the user has to express his definitions by the `\newtheoremstyle` command provided by `ntheorem.sty`, including the use of `\theoremheaderfont` and `\theorembodyfont`. The options [`amsthm`] and [`standard`] are in conflict since they both define an environment `proof`.

Thus, we recommend not to use `amsthm`, since the features for defining theorem-like environments in `ntheorem.sty`—following `theorem.sty`—seem to be more intuitive and user-friendly.

3.3 Babel

The [`thref`] option interferes with the `babel` package, thus in case that `babel` is used, `ntheorem` has to be loaded *after* `babel`.

3.4 Hyperref

Since `hyperref` redefines the LaTeX `\contentsline`-command, it breaks with `ntheorem` below version 1.17. Since version 1.17, the option [`hyperref`] makes `ntheorem` work with `hyperref`. Theoremlists will then get linked list.

WARNING: The definition and redefinition of Theorem List Layouts (see Section 2.5.2) isn't yet working with the `hyperref`-package.

4 Examples

The setting is as follows.

- For Theorems:

      \theoremstyle{marginbreak}
      \theoremheaderfont{\normalfont\bfseries}\theorembodyfont{\slshape}
      \theoremsymbol{\ensuremath{\diamondsuit}}
      \theoremseparator{:}
      \newtheorem{Theorem}{Theorem}

- For Lemmas:

      \theoremstyle{changebreak}
      \theoremsymbol{\ensuremath{\heartsuit}}
      \theoremindent0.5cm
      \theoremnumbering{greek}
      \newtheorem{Lemma}{Lemma}

- For Corollaries:

  ```
  \theoremindent0cm
  \theoremsymbol{\ensuremath{\spadesuit}}
  \theoremnumbering{arabic}
  \newtheorem{Corollary}[Theorem]{Corollary}
  ```

- For Examples:

  ```
  \theoremstyle{change}
  \theorembodyfont{\upshape}
  \theoremsymbol{\ensuremath{\ast}}
  \theoremseparator{}
  \newtheorem{Example}{Example}
  ```

- For Definitions:

  ```
  \theoremstyle{plain}
  \theoremsymbol{\ensuremath{\clubsuit}}
  \theoremseparator{.}
  \theoremprework{\bigskip\hrule}
  \theorempostwork{\hrule\bigskip}
  \newtheorem{Definition}{Definition}
  ```

- For Proofs (note that `theoremprework` and `theorempostwork` are reset – proofs do not have lines above and below):

  ```
  \theoremheaderfont{\sc}\theorembodyfont{\upshape}
  \theoremstyle{nonumberplain}
  \theoremseparator{}
  \theoremsymbol{\rule{1ex}{1ex}}
  \newtheorem{Proof}{Proof}
  ```

Note, that parts of the setting are inherited. For instance, the fonts are not reset before defining "Lemma", so the font setting of "Theorem" is used.

1 Example (Simple one) The first example is just a text.
In the next examples, it is shown how an endmark is put at a displaymath, a single equation and both types of eqnarrays. ∗

1 Theorem (Long Theorem):
The examples are put into this theorem environment.
The next example will not appear in the list of examples since it is written as

```
\begin{Example*} ... \end{Example*}
```

2 Example (Ending with a displayed formula) Look, the endmark is really at the bottom of the line:

$$f^{(n)}(z) = \frac{n!}{2\pi i} \int\limits_{\partial D} \frac{f(\zeta)}{(\zeta - z)^{n+1}} d\zeta$$

∗

At this point, we add an additional entry without number in the Example list:

```
\addtheoremline*{Example}{Extra Entry}
```

α Lemma (Display with array):
Lemmata are indented and numbered with greek symbols. Also for displayed arrays of this form, it looks good:

```
\[\begin{array}{l}
    a = \begin{array}[t]{l}
         first\ line \\
         second\ line
       \end{array}%
    \mbox{try to put this text in the lowest line}\end{array}\]
```

Just try to get this with the presented array structure ... without using dirty tricks, you can position the outer array either [t], [c], or [b], and you will not get the desired effect.

$$a = \quad first\ line \quad \text{try to put this text in the lowest line}$$
$$second\ line \hspace{7cm} \heartsuit$$

β Lemma (Equation):
For `equations`, we decided to put the endmark after the equation number, which is vertically centered. Currently, we do not know, how to get the equation number centered and the endmark at the bottom (one has to know the internal height of the math material) ... If anyone knows, please inform us.

$$\int_\gamma f(z)\,dz := \int_a^b f(\gamma(t))\gamma'(t)\,dt \qquad (1) \quad \heartsuit$$

With the `break`-theoremstyles, if the environment is labeled and written as

```
\begin{Lemma}[Breakstyle]\label{breakstyle}
```

γ Lemma (Breakstyle):
you see, there is a leading space ...
If a percent (comment) (or an explicit `\ignorespaces`) is put directly after the label, e.g.

```
\begin{Lemma}[Breakstyle]\label{breakstyle}%,
```

the space disappears.
From the predefined styles, this is exactly the case for the break-styles. That's no bug, it's LATEX-immanent.
The example goes on with an `eqnarray`:

$$f(z) \quad = \quad \frac{1}{2\pi i}\int_{\partial D}\frac{f(\zeta)}{\zeta - z}d\zeta \qquad (2)$$

$$= \quad \frac{1}{2\pi}\int_0^{2\pi} f(z_0 + re^{it})dt \qquad (3)$$
$$\heartsuit$$

PROOF (OF NOTHING)

$$f(z) = \frac{1}{2\pi i} \int_{\partial D} \frac{f(\zeta)}{\zeta - z} d\zeta$$

$$= \frac{1}{2\pi} \int_0^{2\pi} f(z_0 + re^{it}) dt \qquad \blacksquare$$

That's it (the end of the Theorem). $\qquad\qquad\qquad\qquad \diamondsuit$

If there are some environments in the same thm-environment, the last gets the endmark:

Definition 1 (With a list).

$$\int_\gamma f(z)\, dz := \int_a^b f(\gamma(t))\gamma'(t)\, dt \qquad\qquad (4)$$

- you've seen, how it works for text and

- math environments,

- and it works for lists. $\qquad\qquad\qquad\qquad\qquad\qquad\clubsuit$

---

2 Corollary (Q.E.D.):
And here is a trivial corollary, which is ended by `\qedsymbol{\textrm{q.e.d}}`
and `\qed`*.* $\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad q.e.d$

3 Example

$$f^{(n)}(z) = \frac{n!}{2\pi i} \int_{\partial D} \frac{f(\zeta)}{(\zeta - z)^{n+1}} d\zeta$$

If there is some text after an environment, the endmark is put after the text. $\quad *$

The next one is done by the following sequence. Note, that `~\hfill~` is inserted to prevent LaTeX from using its nested list management (a verbatim is also a trivlist), i.e. this causes LaTeX to start the `verbatim`-Part in a new line.

```
\begin{Example}
~\hfill~
\begin{verbatim}
And, it also works for verbatim
... when the \end{verbatim} is in the
same line as the text ends. \end{verbatim}
                          ^ this space is important !!
\end{Example}
```

4 Example (Using `verbatim`)

```
And, it also works for verbatim
... when the end{verbatim} is in the
same line as the text ends.                                    *
```

There must be no empty line in the input before the `\end{theorem}` (since then, the end mark is ignored)

```
\begin{Theorem}
some text ... but no end mark

\end{Theorem}
```

3 Theorem:
some text ... but no end mark

Now, there is a corollary which should appear with a different name in the list of corollaries:

```
\begin{Corollary*}[title in text]\label{otherlabel}
...
\end{Corollary*} \addtheoremline{Corollary}{title in list}
```

4 Corollary (title in text):
let's do something weird:

<div align="center">

It also works in the
center
environment.   ♠

</div>

5 Theorem (Quote):
> *In quote environments, the text is normally indented from left and right*
> *by the same space. The endmark is not indented from the right margin,*
> *i.e., it is typeset to the right margin of the surrounding text.*   ◇

Here is an example for turning off the endmark automatics and manual handling:

```
\begin{Theorem}[Manual End Mark]\label{somelabel}
a line of text with a manually set endmark \hfill\TheoremSymbol \\
some more text, but no automatic endmark set. \NoEndMark
\end{Theorem}
```

6 Theorem (Manual End Mark):
a line of text with a manually set endmark   ◇
some more text, but no automatic endmark set.

Also, one should note, that `\hfill` is inserted to set the endmark at the right margin.

5 Example (Quickie) It also works for short one's.   ∗

If you are tired of the greek numbers and the indentation for lemmata ... you can redefine it:

```
\theoremstyle{changebreak}
\theoremheaderfont{\normalfont\bfseries}\theorembodyfont{\slshape}
\theoremsymbol{\ensuremath{\heartsuit}}
\theoremsymbol{\ensuremath{\diamondsuit}}
```

```
\theoremseparator{:}
\theoremindent0.5cm
\theoremnumbering{arabic}
\renewtheorem{Lemma}{Lemma}
```

4 Lemma:
another lemma, with arabic numbering ... note that the numbering continues. ◇

the optional argument (i.e. the 'theorem'-name) can be accessed by \⟨*env*⟩**name**.

```
\begin{Theorem}[somename]
Obviously, we are in Theorem~\Theoremname.
\end{Theorem}
```

7 Theorem (somename):
Obviously, we are in Theorem somename. ◇

This feature can e.g. be used for automatically generating executable code and a commented solution sheet:

```
\begin{exercise}[quicksort]
⟨the exercise text⟩
\begin{verbatimwrite}{solutions/\exercisename.c}
⟨C-code⟩
\end{verbatimwrite}
\verbatiminput{solutions/\exercisename.c}
\end{exercise}
```

This will write the C-code to a file `solutions/quicksort.c` and type it also on the solution sheet.
Now, we define an environment `KappaTheorem` which uses the same style parameters as Theorems and is numbered together with Corollaries (Theorems are also numbered with Corollaries). Note that we define a complex header text and a complex end mark.
```
\theoremclass{Theorem}
\theoremsymbol{\ensuremath{a\atop b}}
\newtheorem{KappaTheorem}[Corollary]{\(\kappa\)-Theorem}
```

8 κ-Theorem (1st κ-Theorem):
That's the first Kappa-Theorem. $\begin{smallmatrix}a\\b\end{smallmatrix}$

4.1   Extended Referencing Features

The standard `\label` command is extended by an optional argument which is intended to contain the "name" of the structure which is labeled, allowing more comfortable referencing; e.g., this section has been started with

```
\subsection*{Extended Referencing Features}%
\label{sec-ExtRef}[Section]
```

As already stated, for theorem-like environments the optional argument is filled in automatically, i.e.,

```
\begin{Theorem}[Manual End Mark]\label{somelabel}
```

(cf. page 17) is equivalent to

```
\begin{Theorem}[Manual End Mark]\label{somelabel}[Theorem]
```

`\thref{`⟨*label*⟩`}` additionally outputs the contents of the optional argument which has been associated with ⟨*label*⟩:

```
This is \thref{sec-ExtRef}
A theorem end mark has been set manually in \thref{somelabel}.
A center environment has been shown in \thref{otherlabel}.
The first Kappa-Theorem has been given in \thref{kappatheorem1}.
```

generates

> This is Section 4.1.
> A theorem end mark has been set manually in Theorem 6. A center environment has been shown in Corollary 4. The first Kappa-Theorem has been given in κ-Theorem 8.

Here one must be careful that the handling of the optional argument is automated only for environments defined by `\newtheorem`, i.e., *not* for sectioning, equations, or enumerations.

Calling `\thref{`⟨*label*⟩`}` for a label which has been set without an optional argument can result in different unintended results: If ⟨*label*⟩ is not inside a theorem-like environment, an error message is obtained, otherwise the type of the surrounding theorem-like environment is output, e.g., calling `\thref{label}` then results in "Theorem ⟨*number*⟩"! Additionally, currently there is no support for multiple references such as "see Theorems 5 and 7" (this would require plural-forms for different languages and handling of `\ref`-lists, probably splitting into different sublists for different environments)[4].

4.2   Framed and Shaded Theorems

Framed theorem classes are defined as follows:

```
\theoremclass{Theorem}
\theoremstyle{break}
\newframedtheorem{importantTheorem}[Theorem]{Theorem}
```

defines important theorems to use the same design as for theorems (except that the break header style is used except the margin header style), number them with the same counter, and put a frame around them:
An instance is created by

```
\begin{importantTheorem}[Important Theorem]
This is an important theorem.
\end{importantTheorem}
```

> **Theorem 9 (Important Theorem):**
> *This is an important theorem.*

---

[4]If someone is interested in programming this, please contact us; it seems to be algorithmically easy, but tedious.

More important theorems are shaded – by default in grey:

```
\theoremclass{Theorem}
\theoremstyle{break}
\newshadedtheorem{moreImportantTheorem}[Theorem]{Theorem}
\begin{moreImportantTheorem}[More Important Theorem]
This is a more important theorem.
\end{moreImportantTheorem}
```

Theorem 10 (More Important Theorem):
This is a more important theorem.   ◊

Even more important theorems are shaded in red:

```
\theoremclass{Theorem}
\theoremstyle{break}
\shadecolor{red}
\newshadedtheorem{evenMoreImportantTheorem}[Theorem]{Theorem}
\begin{evenMoreImportantTheorem}[Even More Important Theorem]
This is an even  more important theorem.
\end{evenMoreImportantTheorem}
```

Theorem 11 (Even More Important Theorem):
This is an even more important theorem.   ◊

Most important theorems get a framed, blue colored box with a shadow. Here, \def\theoremframecommand is used:

```
\theoremclass{Theorem}
\theoremstyle{break}
\shadecolor{red}
\def\theoremframecommand{%
     \psshadowbox[fillstyle=solid,fillcolor=blue,linecolor=black]}
\newshadedtheorem{MostImportantTheorem}[Theorem]{Theorem}
\begin{MostImportantTheorem}[Most Important Theorem]
This is a most important theorem.
\end{MostImportantTheorem}
```

Theorem 12 (Most Important Theorem):
This is a most important theorem.   ◊

4.3   Lists of Theorems and Friends

Note, that we put the following lists into the `quote`-environment to emphazise them from the surrounding text. So the lists are indented slightly at the margin.
With

```
\addtotheoremfile{Added into all theorem lists},
```

in every list, an additional line of text would be inserted. But it isn't actually done
in this documentation since we want to use different list formats.
Only for the list of Examples, this one is added:

```
\addtotheoremfile[Example]{Only concerning Example lists}
```

With

```
\theoremlisttype{all}
\listtheorems{Lemma},
```

all lemmas are listed:

α	Display with array	15
β	Equation	15
γ	Breakstyle	15
4		18
5		24
6		25

From the examples, only those are listed which have an optional name:

```
\theoremlisttype{opt}
\listtheorems{Example}
```

leads to

0	Extra Entry with number	9
	Extra Entry	9
1	Simple one	14
	Extra Entry	15
4	Using `verbatim`	16
5	Quickie	17
	Only concerning Example lists	

One should note the line *Only concerning example lists*, which was added by the
\addtotheoremfile-statement above.
For the next list, another layout, using the `tabular`-environment, is defined:

```
\newtheoremlisttype{tab}%
  {\begin{tabular*}{\linewidth}{@{}lrl@{\extracolsep{\fill}}r@{}}}%
  {##1&##2&##3&##4\\}%
  {\end{tabular*}}
```

Thus, by saying

```
\theoremlisttype{tab}
\listtheorems{Theorem,importantTheorem,moreImportantTheorem,
              evenMoreImportantTheorem,MostImportantTheorem,Lemma},
```

theorems (of all importance levels) and lemmata are listed:

LaTeX-lists can also be used to format the theoremlist. The input

```
\newtheoremlisttype{list}%
  {\begin{trivlist}\item}
  {\item[##2 ##1:]\ ##3\dotfill ##4}%
  {\end{trivlist}}
\theoremlisttype{list}
\listtheorems{Corollary}
```

leads to

In this example, after the item, $\backslash_{\sqcup}$ is used instead of $_{\sqcup}$, because in the latter case, `\dotfill` will produce an error if the optional argument (`##3`) is missing.

5 The End Mark Algorithm

5.1 The Idea

The handling of endmarks with `thmmarks.sty` is based on the same two-pass principle as the handling of labels: the necessary information about endmarks is contained in the `.aux` file.

With `thmmarks.sty`, TEX is always aware whether it is in some theorem-like environment. There, potential positions for endmarks can be

1. at the end of simple text lines in open text,

2. at the end of displaymaths,

3. at the end of equations or equationarrays, or

4. at the end of text lines at the end of lists (or, more general, `trivlists`, such as `verbatim` or `center`).

The problem is, that in the cases (2)–(4), the endmarks has to be placed in a box which is already shipped out, when `\end{...}` is processed. Thus, in those situations, TeX needs to know from the `.aux` file, whether is has to put an endmark. When TeX is in a theorem-like environment and comes to one of the points mentioned in (2)–(4), and the `.aux` file says that there is an endmark, then it is put there. Anyway, it maintains a counter of the potential positions of an end mark in the current theorem-like environment. When it comes to an `\end{theorem}`, it looks if it is in situation (1) (then the endmark is simply put at the end of the current line). Otherwise, the last horizontal box is already shipped out (thus it contains a situation (2)–(4)) and the endmark must be set in it. In this case, a note is written in the `.aux` file, where the endmark actually has to be set (ie, at the latest potential point for setting an endmark inside the theorem).

5.2 The Realization

Let $\langle env \rangle$ be a theorem-like environment. Then, additional to the counter $\langle env \rangle$, TeX maintains two counters `curr`$\langle env \rangle$`ctr` and `end`$\langle env \rangle$`ctr`. In the ith environment of type $\langle env \rangle$, `curr`$\langle env \rangle$`ctr`$= i$ (the LaTeX counter $\langle env \rangle$ cannot be used since a) environments can use the counter of other environments, and b) often counters are reinitialized inside a document). `end`$\langle env \rangle$`ctr` counts the potential situations for putting an endmark inside an environment. It is set to 1 when starting an environment. Each time, when a situation (2)–(4) is reached, the command

> `\mark<\thm@romannum{curr`env`ctr}>`$\langle env \rangle$`<\thm@romannum{end`$\langle env \rangle$`ctr}>`

is called (where `\thm@romannum` just writes the value of a counter as its roman numeral representation, e.g., 17 as xvii). ($<$`\thm@romannum{curr`$\langle env \rangle$`ctr}>`$\langle env \rangle$`<\thm@romannum{end`$\langle env \rangle$`ctr}>` uniquely identifies all situations (2)–(4) in a document).
If at this position an endmark has to be set,

> `\mark<\thm@romannum{curr`$\langle env \rangle$`ctr}>`$\langle env \rangle$`<\thm@romannum{end`$\langle env \rangle$`ctr}>`

is defined in the `.aux` file to be `\end`$\langle env \rangle$`Symbol`, otherwise it is undefined and simply ignored.
When TeX comes to an `\end{`$\langle env \rangle$`}`, it looks if it is in situation (1). If so, the endmark is simply put at the end of the current line. Otherwise,

> `\def\mark<\thm@romannum{curr`env`ctr}>`$\langle env \rangle$`%`
> `<\thm@romannum{end`$\langle env \rangle$`ctr}>{`$\langle env \rangle$`Symbol}`

is written to the `.aux` file for setting the endmark at the latest potential position inside the theorem in the next run.

13 Theorem (Correctness):
1. For a `.tex` file, which does not contain nested theorem-like environments of the same type, in the above situation, the following holds: When compiling, at the ith situation in the jth environment of type $\langle env \rangle$, `mark j $\langle env \rangle$ i` is handled.

For `.tex` *files which contain nested theorem-like environments of the same type,* `mark` k $\langle env \rangle$ l *is handled, where k is the number of the latest environment of type $\langle env \rangle$ which has been called at this moment, and l is the number of situations (2)–(4) which have occurred in environments of type $\langle env \rangle$ since the the kth* `\begin{`$\langle env \rangle$`}`.

2. *When finishing an environment, either an endmark is set directly (when in a text line) or an order to put the end symbol at the latest potential position is written to the* `.aux` *file.* ◇

14 Theorem (Completeness):
The handling of endmarks is complete wrt. plain text, `displaymath`, `equation`, `eqnarray`, `eqnarray*`, *and all environments ended by* `endtrivlist`, *including* `center` *and* `verbatim`. ◇

So, where can be bugs ?

- in the plain TeX handling of endmarks,

- in some special situations which have not been tested yet,

- in some special environments which have not been tested yet.

- in the `amsmath` environments. We seldom use them, so we do not know their pitfalls, and we ran only general test cases.

6 Problems and Questions

6.1 Known Limitations

- Since `ntheorem.sty` uses the `.aux` file for storing information about the positions of endmarks, LaTeX must be run twice for correctly setting the endmarks.

- Since `ntheorem.sty` uses the `.aux` file for storing information about lists in the `.thm` file, a minimum of two runs is needed. If theorems move in any of these runs up to five runs can be needed to generate correct lists.

- Since we need to expand the optional argument of theorems in various ways for the lists, we decided to copy the text verbatim into the `.thm` file. Thus, if you use things like `\thesection` etc., the list won't show the correct text. Therefore you shouldn't use any command that needs to be expanded.

- In nested environments ending at the same time, only the endmark for the inner environment is set, as the following example shows:

```
\begin{Lemma}
 Some text.
 \begin{Proof} The Proof \end{Proof}
\end{Lemma}
```

yields to

5 Lemma:
Some text.

PROOF The Proof ∎

You can handle this by specifying something invisible after the end of the inner theorem. Then the endmark for the outer theorem is set in the next line:

```
\begin{Lemma}
 Some text.
 \begin{Proof} The Proof \end{Proof}~
\end{Lemma}
```

yields to

6 Lemma:
Some text.

PROOF The Proof ∎

◇

- Document option `fleqn` is problematic: `fleqn` handles equations not by `$$` but by lists (check what happens for

  ```
  \begin{theorem} \[ displaymath \] \end{theorem}
  ```

  in standard LaTeX: The displaymath is *not* set in an own line). Also, for long formulas, the equation number and the endmark are smashed into the formula at the right text margin.

- Naturally, `ntheorem.sty` will not work correctly in combination with other styles which change the handling of

  1. theorem-like environments, or
  2. environments concerned with the handling of endmarks, e.g. `\[...\]`, `eqnarray`, etc.

- `ntheorem.sty` is compatible with Frank Mittelbach's `theorem.sty`, which is the most widespread style for setting theorems.

  It cannot be used *with* `theorem.sty`, but it can be used instead of it.

6.2 Known "Bugs" and Problems

- Ending a theorem *directly* after the text, e.g.

  ```
  \begin{Theorem} text\end{Theorem}
  ```

  suppresses the endmark:

15 Theorem:
text

  Therefore a space or a newline should be inserted before `\end{...}`.

- With theoremstyle break, if the linebreak would cause ugly linebreaking in the following text, it is suppressed.

6.3 Open Questions

- For `equations`, we decided to put the endmark after the equation number, which is vertically centered. Currently, we do not know, how to get the equation number centered and the endmark at the bottom (one has to know the internal height of the math material).

- The placement of endmarks is mainly based on a check whether LaTeX is in an ordinary text line when encountering an end-of-environment. This question is *partially* answered by `\ifhmode`: In a text line, LaTeX is always in `\hmode`. But, after an displaymath, LaTeX is also in `\hmode`. Thus, additionally `\lastskip` is checked: after a displaymath, `\lastskip`=0 holds. In most situations, when text has been written into a line, $\mathtt{\backslash lastskip} \neq 0$. But, this does not hold, if the source code is of the following form: `...text\label{bla}`: then, `\lastskip`=0. In those situations, the endmark is suppressed.
  ?? How can it be detected whether LaTeX has just ended a displaymath?

- The above problem with the label: The break style enforces a linebreak by `\hfill\penalty-8000` after the `\trivlist`-item. Thus, TeX gets back into the horizontal mode. The label places a "whatsit" somewhere ... and, it seems that the "whatsit" makes TeX think that there is a line of text.

If someone has a solution to one of those questions, please inform us. (You can be sure to be mentioned in the Acknowledgements.)

7 Code Documentation

7.1 Documentation of the Macros

```
1 \typeout{Style '\basename', Version \fileversion\space <\filedate>}
2 \ProvidesPackage{ntheorem}[\filedate \space\fileversion]
3 \newif\if@thmmarks\@thmmarksfalse
4 \newif\if@thref\@threffalse
5 \newif\ifthm@tempif
```

general setup.

7.1.1 Thmmarks-Related Stuff

```
1 \DeclareOption{thmmarks}{%********************************
2 \PackageInfo{\basename}{Option 'thmmarks' loaded}%
3 %
4 \@thmmarkstrue
5 \newcounter{endNonectr}
6 \newcounter{currNonectr}
7 \newif\ifsetendmark\setendmarktrue
```

activate placement of endmarks and define counters for upper level.
`\ifsetendmark`: true if an endmark has to be set in a complex situation which must be handled by the `.aux` file. For further comments see `\@endtheorem`.

`\thm@romannum` The functionality of `latex.ltx`'s `\roman` command converts numbers into strings, e.g., 17 into xvii. It is used to put notes into the `.aux` file. It must be locally defined, just duplicating the definition of `\roman` in latex.ltx since some packages redefine `\roman`:

```
8 \gdef\thm@romannum#1{\expandafter\thm@roman@num\csname c@#1\endcsname}%
9 \gdef\thm@roman@num#1{\romannumeral #1}%
```

In the following, all relevant environments are changed for handling potential end mark positions:

Changes to List Environment
Original: ltlists.dtx

\endtrivlist Replaces LaTeX's \endtrivlist. An augmented functionality of LaTeX's \endtrivlist is contained in \@endtrivlist.

```
10 \gdef\endtrivlist{%
11   \@endtrivlist{\PotEndMark{\unskip\nobreak\hfill\nobreak}}}
```

At an \endtrivlist (which is called at the end of \list environments and several other environments), \@endtrivlist is called to end the \trivlist and set a potential position for an endmark at the end of the line if TeX is in a text line.

\@endtrivlist A new command] which augments LaTeX's functionality of \endtrivlist by checking if an end mark has to be set:

```
12 \gdef\@endtrivlist#1{%  % from \endtrivlist
13   \if@inlabel \indent\fi
14   \if@newlist \@noitemerr\fi
15   \ifhmode
16     \ifdim\lastskip >\z@ #1\unskip \par  %<<<<<<<<<<<<<<<<<<<<<<
17        \else \unskip \par \fi
18     \fi
19   \if@noparlist \else
20     \ifdim\lastskip >\z@
21       \@tempskipa\lastskip \vskip -\lastskip
22       \advance\@tempskipa\parskip \advance\@tempskipa -\@outerparskip
23       \vskip\@tempskipa
24     \fi
25     \@endparenv
26   \fi}
```

New: parameter #1.
#1 is executed when the \trivlist ends with a text line (ie the endmark can be put simply at the end of the line):
Line 16: case split: if in hmode and \lastskip > 0, then TeX is in a text line, the endmark is set here.

Changes to Math Environments
Original: ltmath.dtx

\endequation For equations, end marks are placed behind the equation number:

```
27 \gdef\SetMark@endeqn{\quad}%  as default, cf. option leqno
28 \gdef\endequation{\eqno \hbox{\@eqnnum \PotEndMark{\SetMark@endeqn}}%
29     $$\global\@ignoretrue}
```

Line 27: As default, work for equation numbers at the right: Then, a \quad is placed between equation number and endmark.

Line 28: In addition to the equation number (set by `\@eqnnum` at the right of the line) `\SetMark@endeqn` is carried out.

`\[`   If an end mark is set, a displaymath is put into box such that the end marks appears at its bottom level at the right. Thus, also the definition of `\[` has to be changed:

```
30 \gdef\[{%
31    \relax\ifmmode
32       \@badmath
33    \else
34       \ifvmode
35          \nointerlineskip
36          \makebox[.6\linewidth]%
37       \fi
38       $$\stepcounter{end\InTheoType ctr}%
39          \@ifundefined{mark\thm@romannum{curr\InTheoType ctr}%
40                      \InTheoType\thm@romannum{end\InTheoType ctr}}{\relax}%
41             {\ifx\csname\InTheoType Symbol\endcsname\@empty\else
42                \boxmaxdepth=.5ex\begin{array}[b]{@{}l}%
43                \boxmaxdepth=\maxdimen\displaystyle\fi}%
44          \addtocounter{end\InTheoType ctr}{-1}%
45          %%$$ BRACE MATCH HACK
46    \fi}
```

Lines 31–37, 45, 46: the old definition.

Lines 38–41: The end position of a displaymath inside a theorem-environment corresponds to `end\InTheoType ctr`+1. An endmark has to be set there, if
$$\mark<\thm@romannum{curr\#1ctr}>\#1 <\thm@romannum{end\#1ctr}+1 >$$
is defined and not the empty symbol.

Lines 42–43: If so, the whole displayed stuff is put in an array with maximal depth 0.5`ex` and vertically adjusted with its bottom line (then, the endmarks will appear adjusted to its bottom line).

Line 44: The counter has to be re-decremented.

`\]`   At the end of a displaymath, the end marks is set at its bottom level:

```
47 \gdef\]{%
48       \stepcounter{end\InTheoType ctr}%
49          \@ifundefined{mark\thm@romannum{curr\InTheoType ctr}%
50                      \InTheoType\thm@romannum{end\InTheoType ctr}}{\relax}%
51             {\ifx\csname\InTheoType Symbol\endcsname\@empty\else
52                \end{array}\fi}%
53          \addtocounter{end\InTheoType ctr}{-1}%
54    \relax\ifmmode
55       \ifinner
56          \@badmath
57       \else
58          \PotEndMark{\eqno}\global\@ignoretrue$$%%$$ BRACE MATCH HACK
59       \fi
60    \else
61       \@badmath
62    \fi
63    \ignorespaces}
```

Lines 48–53: Look, if an endmark has to be set in this displaymath (analogous to lines 38–44 of `\def\[`) If so, there is an inner array which has to be closed (line

52).

Lines 54–63: the old definition.

Line 58: changed to set an endmark at the right of the line if necessary (this is done by `\eqno`).

\endeqnarray   For `\eqnarray`s, the end marks is set below the number of the last equation:

```
64 \gdef\SetMark@endeqnarray#1{\llap{\raisebox{-1.3em}{#1}}}
65 \gdef\endeqnarray{%
66     \global\let\Oldeqnnum=\@eqnnum
67     \gdef\@eqnnum{\Oldeqnnum\PotEndMark{\SetMark@endeqnarray}}%
68     \@@eqncr
69     \egroup
70     \global\advance\c@equation\m@ne
71   $$\global\@ignoretrue
72     \global\let\@eqnnum\Oldeqnnum}
```

Line 64: As default work for equation numbers at the right: Then, the endmark is placed below the last equation number at the right margin.

New: Lines 66, 67, 72:

Line 66: save `\@eqnnum`.

Line 67: define `\@eqnnum` to carry out `\Oldeqnnum`, then a potential endmark position is handled: if an endmark is set, between the equation number and the endmark, the command sequence `\SetMark@endeqnarray` is carried out – there, since `\SetMark@endeqnarray` is a function of one argument, the endmark will be this argument.

Lines 68–71: from `latex.ltx`. Line 68 sets the equation number.

Line 72: restore `\@eqnnum`.

\endeqnarray*   In an `\eqnarray*`, the end mark is set at the right of the last equation:

```
73 \@namedef{endeqnarray*}{%
74     %     from \@@eqncr:
75     \let\reserved@a\relax
76     \ifcase\@eqcnt \def\reserved@a{& & &}\or \def\reserved@a{& &}%
77     \or \def\reserved@a{&}\else
78       \let\reserved@a\@empty
79       \@latex@error{Too many columns in eqnarray environment}\@ehc\fi
80     \reserved@a {\normalfont \normalcolor \PotEndMark{}}%
81     \global\@eqnswtrue\global\@eqcnt\z@\cr
82     %
83       \egroup
84       \global\advance\c@equation\m@ne
85     $$\global\@ignoretrue}
```

This is just LaTeX's `\endeqnarray` where lines 75–81 are inserted from `\@@eqncr` and augmented (line 80) to set a potential endmark (with no additional commands) at the end of the current line.

Changes to Tabbing Environment
Original: lttab.dtx

\endtabbing   Here, the `\endtrivlist` modification is not sufficient: LaTeX is not in hmode when it calls `\endtrivlist` from `\endtabbing`; additionally, `\@stopline` already outputs

a linebreak. Thus, the end mark is inserted *before* `\@stopline` at the right margin
(using `\'`).

```
86 \gdef\endtabbing{%
87   \PotEndMark{\'}\@stopline\ifnum\@tabpush >\z@ \@badpoptabs
88   \fi\endtrivlist}
```

Changes to Center Environment
Original: ltmiscen.dtx

`\endcenter` In LaTeX, `\endcenter` just calls `\endtrivlist`. Here, the situation is more complex
since the the endmark has to be put in the last line without affecting its centering:
if in a text line (only then, here is a potential endmark position):

```
89 \gdef\endcenter{%
90   \@endtrivlist
91     {\PotEndMark{\rightskip0pt%
92         \settowidth{\leftskip}%
93         { \csname mark\thm@romannum{curr\InTheoType ctr}\InTheoType
94                 \thm@romannum{end\InTheoType ctr}\endcsname}%
95         \advance\leftskip\@flushglue\hskip\@flushglue}}}
```

The `\rightskip` of the line is set to 0, `\leftskip` is set to the width of one space
(since on the right, one space is added after the text) plus the endmark and infinitely
stretchable glue (`\@flushglue`), and also the line is continued with `\@flushglue`
(the actual position is one space after the text), and then the endmark is placed
(by `\PotEndMark`).

Handling of Endmarks

`\@endtheorem-thmmarks` `\@endtheorem` is called for every `\end{`⟨*env*⟩`}`, where ⟨*env*⟩ is a theorem-like envi-
ronment. `\@endtheorem` is extended to organize the placement of the corresponding
end mark (`\InTheoType` gives the innermost theorem-like environment, i.e. the one
to be ended):

```
96 \gdef\@empty{}
97 \gdef\@endtheorem{%
98   \expandafter
99   \ifx\csname\InTheoType Symbol\endcsname\@empty\setendmarkfalse\fi
100  \@endtrivlist
101    {\ifsetendmark
102     \unskip\nobreak\hfill\nobreak\csname\InTheoType Symbol\endcsname
103     \setendmarkfalse \fi}%
104  \ifsetendmark\OrganizeTheoremSymbol\else\global\setendmarktrue\fi
105  \csname\InTheoType @postwork\endcsname
106  }
```

Lines 98, 99: if the end symbol of the environment ⟨*env*⟩ to be closed is empty,
  simply no end symbol has to be set (it makes a difference, if no end symbol is
  set, or if an empty end symbol is set).

Lines 100, 104: (originally, it calls `\endtrivlist`):

Lines 100, 102, 103: `\@endtrivlist` is called to put ⟨*env*⟩`Symbol` at the end of the
  line and set `setendmark` to false if TeX is in a text line and `setendmark` is true.
  At this point, `setendmark` is false iff the user has disabled it locally or the end
  symbol is empty.

Line 101: the endmark is not set, if `setendmark` is false.

Line 104: if `setendmark` is true, the correct placement of the end symbol is organized, else (ie either `setendmarkfalse` is set by the user, or the endmark is already set by `\@endtrivlist`) reset `setendmark` to true.
For further comments see `\@endtrivlist` and `\OrganizeTheoremSymbol`.

The construction in line 102 guarantees that the endmark is put at the end of the line, even if it is the only letter in this line.

`\NoEndMark` By `\NoEndMark`, the automatical setting of an end mark is blocked for the *current* environment.

107 `\gdef\NoEndMark{\global\setendmarkfalse}`

set `setendmark` to false. It is automatically reset to `true` after the end of the current environment.

`\qed` With `\qed`, the user can locally change the end symbol to appear:

108 `\gdef\qed{\expandafter\def\csname \InTheoType Symbol\endcsname`
109 `        {\the\qedsymbol}}%`

When calling `\qed`, the end symbol of the innermost theorem-like environment at that time is set to the value stored in `\qedsymbol` at that time.

`\PotEndMark` Handling a potential endmark position:

110 `\gdef\PotEndMark#1{\SetEndMark{\InTheoType}{#1}}%`

Argument: ⟨*cmd_seq*⟩:=`#1` is a command sequence to be executed when setting the endmark.
It adds the current theorem type ⟨*env*⟩ to the parameters, and calls
`\PotEndMark{`⟨*env*⟩`}{`⟨*cmd_seq*⟩`}`.

`\SetEndMark` `\SetEndMark` sets an endmark for an environment. It is called by `\PotEndMark`.

111 `\gdef\SetEndMark#1#2{%`
112 `    \stepcounter{end#1ctr}%`
113 `    \@ifundefined{mark\thm@romannum{curr#1ctr}#1\thm@romannum{end#1ctr}}%`
114 `    {\relax}%`
115 `    {#2{\csname mark\thm@romannum{curr#1ctr}#1\thm@romannum{end#1ctr}\endcsname`
116 `        \ifdim\rightmargin>\z@\hskip-\rightmargin\fi`
117 `        \hbox to 0cm{}}}}%`

Arguments:
⟨*env*⟩:=`#1`: current theorem-environment.
⟨*cmd_seq*⟩:= `#2`: is a command sequence to be executed when setting the endmark.
Both arguments are transmitted from by `\PotEndMark`.

Line 112: increments `end`⟨*env*⟩`ctr` for preparing the next situation for setting a potential endmark.

Line 113, 114: if

$$\mathtt{\backslash mark{<}\backslash thm@romannum\{curr\langle env\rangle ctr\}{>}\langle env\rangle{<}\backslash thm@romannum\{end\langle env\rangle ctr\}{>}}$$

is undefined – which is the case iff at this position no endmark has to be set –, nothing is done,

Line 115: otherwise, ⟨*cmd_seq*⟩ and then

$$\mathtt{\backslash mark}<\mathtt{\backslash thm@romannum\{curr}\langle env\rangle\mathtt{ctr\}}>\mathtt{\backslash env}\ <\mathtt{\backslash thm@romannum\{end}\langle env\rangle\mathtt{ctr\}}>,$$

which is defined in the `.aux` file to be the end symbol are called.

The construction $\langle cmd\_seq\rangle\mathtt{\{\ldots\}}$ in line 115 allows the handling of the end symbol as an argument of $\langle cmd\_seq\rangle$ as needed for `\endeqnarray`.

Line 116: By `\hskip-\rightmargin\hbox to 0cm{}`, a negative hspace of amount `\rightmargin` is added *after* the end symbol – thus, the symbol is set as there were no right margin (this concerns, e.g., `\quote` environments).

(applied only if `\rightmargin` is more than 0 – otherwise bug if preceding line ends with hyphenation.)

Writing to .aux file. (copied from `\def\label` (ltxref.dtx))

```
118 \newskip\mysavskip
119 \gdef\@bbsphack{%
120     \ifvmode\else\mysavskip\lastskip
121     \unskip\fi}
122 %
123 \gdef\@eesphack{%
124     \ifdim\mysavskip>\z@
125     \vskip\mysavskip \else\fi}
```

Lines 119–121 and 122–124 are similar to `\@bsphack` and `\@bsphack` of latex.ltx. They undo resp. redo the last `skip`.

Note that `@bbsphack` and `@eesphack` are also part of the thref option. Change both if you change them.

`\OrganizeTheoremSymbol` The information for setting the end marks is written to the .aux file:

```
126 \gdef\OrganizeTheoremSymbol{%
127   \@bbsphack
128   \edef\thm@tmp{\expandafter\expandafter\expandafter\thm@meaning
129       \expandafter\meaning\csname\InTheoType Symbol\endcsname\relax}%
130   \protected@write\@auxout{}%
131     {\string\global\string\def\string\mark%
132     \thm@romannum{curr\InTheoType ctr}\InTheoType \thm@romannum{end\InTheoType ctr}%
133     {\thm@tmp}}%
134   \@eesphack}
```

Lines 130–132: Write
$$\mathtt{\backslash global\backslash def\backslash mark}<\mathtt{\backslash thm@romannum\{curr}\langle env\rangle\mathtt{ctr\}}>\ \langle env\rangle\ <\mathtt{\backslash thm@romannum\{end}\langle env\rangle\mathtt{ctr\}}>$$
$\mathtt{\{<}\langle env\rangle\mathtt{Symbol>\}}$ to the `.aux` file.

$\langle env\rangle:=$`\InTheoType` gives the innermost theorem-like environment, i.e. the one the end symbol has to be set for.

```
135 } % end of option [thmmarks]
```

7.1.2 Option leqno to Thmmarks

```
136 \DeclareOption{leqno}{% ********************************************
137   \if@thmmarks
138   \PackageInfo{\basename}{Option 'leqno' loaded}%
139   \gdef\SetMark@endeqn#1{\hss\llap{#1}}
140   \gdef\SetMark@endeqnarray#1{\hss\llap{#1}}
141   \fi}%
```

`leqno` is only active it `thmmarks` is also active.

Line 139, 140: Since with `leqno`, the equation number is placed on the left, after
infinitely stretchable glue, the endmark can be set straight at the right margin.

7.1.3 Option fleqn to Thmmarks

```
142 \DeclareOption{fleqn}{% *********************************************
143 \if@thmmarks
144 \PackageInfo{\basename}{Option 'fleqn' loaded}%
```

`fleqn` is only active it `thmmarks` is also active.

\[Since `fleqn` treats displayed math as trivlists, it's quite another thing:

```
145 \renewcommand\[{\relax
146    \ifmmode\@badmath
147    \else
148    \begin{trivlist}%
149       \@beginparpenalty\predisplaypenalty
150       \@endparpenalty\postdisplaypenalty
151       \item[]\leavevmode
152       \hb@xt@\linewidth\bgroup $\m@th\displaystyle %$
153       \hskip\mathindent\bgroup
154         \stepcounter{end\InTheoType ctr}%
155         \@ifundefined{mark\thm@romannum{curr\InTheoType ctr}%
156                    \InTheoType\thm@romannum{end\InTheoType ctr}}{\relax}%
157           {\ifx\csname\InTheoType Symbol\endcsname\@empty\else
158             \boxmaxdepth=.5ex\begin{array}[b]{@{}l}%
159             \boxmaxdepth=\maxdimen\displaystyle\fi}%
160         \addtocounter{end\InTheoType ctr}{-1}%
161    \fi}
```

Lines 145–153, 161: the old definition.

Line 154–160: if an endmark has to be set in this displaymath, it is put into an array
with depth ≤ 0.5ex, and vertically adjusted to the bottom line.

\] Here, the end mark is placed after a `\hfil` ate the end of the line containing the
displaymath:

```
162 \renewcommand\]{%
163    \stepcounter{end\InTheoType ctr}%
164    \@ifundefined{mark\thm@romannum{curr\InTheoType ctr}%
165               \InTheoType\thm@romannum{end\InTheoType ctr}}{\relax}%
166      {\ifx\csname\InTheoType Symbol\endcsname\@empty\else
167         \end{array}\fi}%
168    \addtocounter{end\InTheoType ctr}{-1}%
169    \relax\ifmmode
170               \egroup $\hfil\PotEndMark{}% $
171            \egroup
172          \end{trivlist}%
173         \else \@badmath
174         \fi}
```

Lines 163–167: Look, if an endmark has to be set in this displaymath. If so, close
the inner array.

Lines 169–174: the old definition.

Line 170: Added `\PotEndMark`.

`\endequation`   for equations, the end mark is also set with the equation number:

```
175 \gdef\endequation{%
176     $\hfil % $
177         \displaywidth\linewidth\hbox{\@eqnnum \PotEndMark{\SetMark@endeqn}}%
178        \egroup
179       \endtrivlist}
```

Line 177: When the equation number is set, also the endmark is set with the same trick as for `\endequation` without `fleqn`.

`\endeqnarray`   When the equation number is set, also the endmark is set with the same trick as for `\endeqnarray` without `fleqn` (see Lines 181, 182, 187):

```
180 \gdef\endeqnarray{%
181     \global\let\Oldeqnnum=\@eqnnum
182     \gdef\@eqnnum{\Oldeqnnum\PotEndMark{\SetMark@endeqnarray}}%
183     \@@eqncr
184     \egroup
185     \global\advance\c@equation\m@ne$$% $$
186     \global\@ignoretrue
187     \global\let\@eqnnum\Oldeqnnum}

188 \fi}% end of option fleqn
```

7.1.4   Extended Referencing Facilities

```
189 \DeclareOption{thref}{%**********************************************
190     \PackageInfo{\basename}{Option 'thref' loaded}%
191 \@threftrue
```

Option "thref" needs a special handling when combined with amsmath. This is also a reason why it is handled first.

`\bbsphack(2)`

```
192 \newskip\mysavskip
193 \gdef\@bbsphack{%
194     \ifvmode\else\mysavskip\lastskip
195     \unskip\fi}
196 %
197 \gdef\@eesphack{%
198     \ifdim\mysavskip>\z@
199     \vskip\mysavskip \else\fi}
```

Note that `@bbsphack` and `@eesphack` are also part of the thmmarks option. Change both if you change them.

`\label`   The original `\label` macro is extended (cf. ltxref.dtx) with an optional argument, containing the type of the labeled construct:

```
200 \def\label#1{%
201   \@ifnextchar[%
202       {\label@optarg{#1}}%
203       {\thm@makelabel{#1}}}
204 %
205 \def\thm@makelabel#1{%
206   \@bbsphack
```

```
207    \edef\thm@tmp{\expandafter\expandafter\expandafter\thm@meaning
208          \expandafter\meaning\csname\InTheoType Keyword\endcsname\relax}%
209    \protected@write\@auxout{}%
210      {\string\newlabel{#1}{{\@currentlabel}{\thepage}}[\thm@tmp]}%
211    \@eesphack}
212 %
213 \def\label@optarg#1[#2]{%
214    \@bsphack
215    \protected@write\@auxout{}%
216      {\string\newlabel{#1}{{\@currentlabel}{\thepage}}[#2]}%
217    \@esphack}
```

thm@makelabel: If no optional argument is given, the keyword of the current envi-
ronment type is used instead.

label@optarg: The original definition, extended with the optional argument which
is appended to the \newlabel-command to be written to the .aux-file.

\newlabel   The original behavior of \newlabel (called when evaluating the .aux-file) is also
adapted.
Original syntax: \newlabel{⟨label⟩}{{⟨section⟩}{⟨page⟩}}
Modified syntax: \newlabel{⟨label⟩} {{⟨section⟩}{⟨page⟩}}[⟨type⟩]
Definition of \newlabel: \def\newlabel{\@newl@bel r}.
Therefore, the modification is encoded into the \@newl@bel macro:

```
218 \def\@newl@bel#1#2#3{%
219    \@ifpackageloaded{babel}{\@safe@activestrue}\relax%
220    \@ifundefined{#1@#2}%
221      \relax
222      {\gdef \@multiplelabels {%
223        \@latex@warning@no@line{There were multiply-defined labels}}%
224      \@latex@warning@no@line{Label '#2' multiply defined}}%
225    \global\@namedef{#1@#2}{#3}%
226    \@ifnextchar[{\set@label@type{#1}{#2}}%]
227                \relax}%
228 \def\set@label@type#1#2[#3]{%
229    \global\@namedef{#1@#2@type}{#3}}
```

the macro is called with three arguments (same as originally):
#1=r,
⟨labelname⟩ := #2 is the label name,
#3 is a pair (section, page-number) consisting of the values needed for \ref and
\pageref, respectively.

Line 219: adaptation to babel

Lines 220–225: The original definition (both standard LATEX and babel).

Line 226: if an optional argument follows (containing the environment-type), con-
tinue with \set@label@type, otherwise return (the original behavior).

Lines 228,229: set \r@⟨labelname⟩@type to the type of the respective environment.

\testdef   A problem occurred, when about 250 labels to theorem-like environments have been
defined: after the end of a document, the .aux file is read once more (to check if
references changed). Here, LATEX redefines \@newl@bel into \@testdef – and LATEX
does not know that ntheorem's \label has an additional optional argument. Thus,
the argument values are not processed, but are output as normal text. Normally,

this did not matter since output has already benn finished by a `\clearpage` in `\end{document}`. For so many labels, a page gets filled and the output routine is called.

```
230 \newcommand\org@testdef{}
231 \let\org@testdef\@testdef
232 \def\@testdef#1#2#3{%
233   \org@testdef{#1}{#2}{#3}%
234   \@ifnextchar[{\@gobbleopt}{}%
235 }
236 \newcommand\@gobbleopt{}
237 \long\def\@gobbleopt[#1]{}
```

Line 233: process the optional argument.

\thref   \thref is an adaptation of \ref:

```
238 \def\thref#1{%
239   \expandafter\ifx\csname r@#1@type\endcsname\None
240     \PackageWarning{\basename}{thref: Reference Type of '#1' on page
241      \thepage \space undefined}\G@refundefinedtrue
242    \else\csname r@#1@type\endcsname~\fi%
243   \expandafter\@setref\csname r@#1\endcsname\@firstoftwo{#1}}
```

Lines 238,243: similar to `\ref`.

Line 219: if a legal theorem type is given, then output `\r@`⟨*labelname*⟩`@type` and avoid linebreaking between the type and the number.

```
244 }% end of option thref ************************************************
```

7.1.5 Option amsmath to Thmmarks

Most of the commands are extensions of commands in `amsmath.sty`.

```
245 \DeclareOption{amsmath}{% ************************************************
246 \if@thref
247 \PackageInfo{\basename}{option 'amsmath' handling for 'thref' loaded}%
```

if `thref` is active, the handling of labels in amsmath equations has also to be adapted.

ams-thref

```
248 \let\ltx@label\label
```

keep the handling of `\label` ... (the one defined above in the thref option).
amsmath implements a special handling of `\label` inside of displaymath environments. It is extended to process the optional argument provided be the thref option:

```
249 \global\let\thm@df@label@optarg\@empty
250 \def\label@in@display#1{%
251     \ifx\df@label\@empty\else
252         \@amsmath@err{Multiple \string\label's:
253             label '\df@label' will be lost}\@eha
254     \fi
255     \gdef\df@label{#1}%
256     \@ifnextchar[{\thm@label@in@display@optarg}{\thm@label@in@display@noarg}%]
257 }
258 \def\thm@label@in@display@noarg{%
```

```
259     \global\let\thm@df@label@optarg\@empty
260 }
261 \def\thm@label@in@display@optarg[#1]{%
262     \gdef\thm@df@label@optarg{#1}%
263 }
```

The contents of `\df@label` is handled when the equation is finished. (Currently) this happens in three macros. The modification consists of the check if `\thm@df@label@optarg` is non-empty (i.e., holds the optional argument), and to handle it.

```
264 \def\endmathdisplay@a{%
265   \if@eqnsw \gdef\df@tag{\tagform@\theequation}\fi
266   \if@fleqn \@xp\endmathdisplay@fleqn
267   \else \ifx\df@tag\@empty \else \veqno \alt@tag \df@tag \fi
268     \ifx\df@label\@empty \else
269       \ifx\thm@df@label@optarg\@empty \@xp\ltx@label\@xp{\df@label}
270               \else \@xp\ltx@label\@xp{\df@label}[\thm@df@label@optarg]\fi
271         \fi
272   \fi
273   \ifnum\dspbrk@lvl>\m@ne
274     \postdisplaypenalty -\@getpen\dspbrk@lvl
275     \global\dspbrk@lvl\m@ne
276   \fi
277 }
278 \def\make@display@tag{%
279     \if@eqnsw
280         \refstepcounter{equation}%
281         \tagform@\theequation
282     \else
283         \iftag@
284             \df@tag
285             \global\let\df@tag\@empty
286         \fi
287     \fi
288     \ifmeasuring@
289     \else
290       \ifx\df@label\@empty\else
291         \ifx\thm@df@label@optarg\@empty \@xp\ltx@label\@xp{\df@label}
292                 \else \@xp\ltx@label\@xp{\df@label}[\thm@df@label@optarg]\fi
293         \global\let\df@label\@empty

312 % end of option amsmath/thref *****************************************
313 \if@thmmarks
314 \PackageInfo{\basename}{option 'amsmath' handling for 'thmmarks' loaded}%
315 \newdimen\thm@amstmpdepth
```

A temporarily used register.

\TagsPlusEndmarks   Since amsmath uses "tags" for setting end marks, some macros are defined which
                     prepare tags which include endmarks:

```
316 \gdef\TagsPlusEndmarks{%
317        \global\let\Old@maketag@@@=\maketag@@@
318        \global\let\Old@df@tag=\df@tag
319        \if@eqnsw\SetTagPlusEndMark
320          \else
321            \iftag@\SetTagPlusEndMark
322              \else\SetOnlyEndMark
323            \fi
324        \fi}
```

Lines 317, 318: store the original macros.

Line 319: if equation numbers are set as default, call \SetTagPlusEndMark to set
         tag and end mark.

Lines 320, 321: if a tag is set manually, call \SetTagPlusEndMark to set tag and end
              mark.

Line 322: otherwise, call \SetOnlyEndMark to set only an end mark.

\SetOnlyEndMark

```
325 \gdef\SetOnlyEndMark{%
326        \global\tag@true
327          \iftagsleft@
328            \gdef\df@tag{\hbox
329                         to \displaywidth{\hss\PotEndMark{\maketag@@@}}}%
330          \else
331            \gdef\df@tag{\PotEndMark{\maketag@@@}}%
332          \fi}
```

Set only an end mark:

Line 326: force setting the end mark as a tag:

Lines 328,329: if tags are set to the left, the tag consists of a \hbox over the whole
             displaywidth, with the (potential) endmark at its right.

Line 331: if tags are set to the right, the tag consists only of the (potential) endmark.

\SetTagPlusEndMark

```
333 \newdimen{\tagwidth}
334 \gdef\SetTagPlusEndMark{%
335        \iftagsleft@
336          \gdef\maketag@@@##1{%
337            \settowidth{\tagwidth}{$##1$}%  %% WM 17.10.2007
```

```
338              \hbox to \tagwidth{%
339                \hbox to \displaywidth{\m@th\normalfont##1%
340                                        \hss\PotEndMark{\hss}}\hss}}%
341            \else
342              \gdef\maketag@@@##1{\hbox{\m@th\normalfont##1%
343                            \llap{\hss\PotEndMark{\raisebox{-1.3em}}}}}}%
344            \fi}
```

Set a tag *and* an end mark:

Lines 334–343: redefine the `\maketag@@@` macro:

Lines 335–339: if tags are set to the left, build a box of the whole displaywidth and put the original tag on the left, and the (potential) endmark at the right. Put this box with width 0 and continue.

Lines 340,341: if the tags are set to the right, the (potential) end mark is put below it.

`\RestoreTags`

```
345 \gdef\RestoreTags{%
346     \global\let\maketag@@@=\Old@maketag@@@
347     \global\let\df@tag=\Old@df@tag}
```

Lines 346,347: restore the original macros.

`\endgather`   In the `gather` environment, just the augmented tag is used:

```
348 \gdef\endgather{%
349     \TagsPlusEndmarks % <<<<<<<<
350     \math@cr
351     \black@\totwidth@
352   \egroup
353   $$%
354   \RestoreTags         % <<<<<<<<
355   \ignorespacesafterend}
356 %
357 \expandafter\let\csname endgather*\endcsname\endgather
```

New:

Line 349: the last tag contains the potential endmark.

Line 354: restore the original macros.

Line 357: Since `let` always takes the expansion of a macro when the let is executed, all let's have to be adjusted (this is the same for all subsequent let-statements).

`\math@cr@@@align`

`\endalign`   `\endalign` also uses the augmented tags:

```
358 \def\endalign{%
359     \ifingather@\else       % <<<<<<<<
360         \TagsPlusEndmarks\fi % <<<<<<<<
361     \math@cr
362     \black@\totwidth@
363   \egroup
364   \ifingather@
365     \restorealignstate@
366     \egroup
367     \nonumber
```

```
368            \ifnum0=`{\fi\iffalse}\fi
369        \else
370            $$%
371            \RestoreTags              % <<<<<<<<
372        \fi
373        \ignorespacesafterend}
```

New:

Lines 359, 360: if the `align` is not inside another environment, its tags have to contain the endmarks.

Line 371: this case, the original macros have to be restored.

```
374 \expandafter\let\csname endalign*\endcsname\endalign
375 \let\endxalignat\endalign
376 \expandafter\let\csname endxalignat*\endcsname\endalign
377 \let\endxxalignat\endalign
378 \let\endalignat\endalign
379 \expandafter\let\csname endalignat*\endcsname\endalign
380 \let\endflalign\endalign
381 \expandafter\let\csname endflalign*\endcsname\endalign
```

Adjust let-statements.

\lendmultline   The `multline` environment has two different `\end` commands, depending if the equation numbers are set on the left or on the right:

```
382 \def\lendmultline@{%
383        \global\@eqnswfalse\tag@false\tagsleft@false
384        \rendmultline@}
```

End of `multline` environment if tags are set to the left: in this case, the last line of a `multline` does not contain a tag. Thus the situation of setting an endmark tag at the right is faked:

Lines 383, 384: display no equation number, don't set an equation tag (but use the tag mechanism for the end mark - see \TagsPlusEndmarks and \SetOnlyEndMark), set it at the right, and call \rendmultline.

\rendmultline   \rendmultline also uses the augmented tags:

```
385 \def\rendmultline@{%
386     \TagsPlusEndmarks           % <<<<<<<<
387     \iftag@
388        $\let\endmultline@math\relax
389           \ifshifttag@
390              \hskip\multlinegap
391              \llap{\vtop{%
392                 \raise@tag
393                 \normalbaselines
394                 \setbox\@ne\null
395                 \dp\@ne\lineht@
396                 \box\@ne
397                 \hbox{\strut@\make@display@tag}%
398              }}%
399           \else
400              \hskip\multlinetaggap
401              \make@display@tag
402           \fi
```

```
403        \else
404            \hskip\multlinegap
405        \fi
406        \hfilneg
407            \math@cr
408        \egroup$$%
409        \RestoreTags}                    % <<<<<<<<<
```
New:

Line 386: last tag contains the potential endmark.

Line 410: restore the original macros

\endmathdisplay

```
410 \def\endmathdisplay#1{%
411        \ifmmode \else \@badmath \fi
412        \TagsPlusEndmarks % <<<<<<<<<
413        \endmathdisplay@a
414        $$%
415        \RestoreTags           % <<<<<<<<<

417        \global\tag@false \global\let\alt@tag\@empty
418        \global\@eqnswfalse
419 }
```

Added Line 413: set potential end mark at bottom niveau of displaymath.

equation

```
420 \renewenvironment{equation}{%
421    \edef\reset@equation{%
422      \@nx\setcounter{equation}{\number\c@equation}}%
423    \refstepcounter{equation}%
424    \st@rredfalse \global\@eqnswtrue
425    \mathdisplay{equation}%
426 }{%
427    \endmathdisplay{equation}%
428    \ignorespacesafterend
429 }
430 \renewenvironment{equation*}{%
431    \st@rredtrue \global\@eqnswfalse
432    \mathdisplay{equation*}%
433 }{%
434    \endmathdisplay{equation*}%
435    \ignorespacesafterend
436 }
```

unchanged from amsmath.sty.

```
437 \fi
438 }% end of option amsmath/thmmarks ************************************
```

7.1.6 Theorem-Layout Stuff

```
439 \let\thm@usestd\@undefined
440 \DeclareOption{standard}{\let\thm@usestd\relax}
441 \let\thm@noconfig\@undefined
```

41

```
442 \DeclareOption{noconfig}{\let\thm@noconfig\relax}
```

Options for selection of a configuration: if no such option is given `ntheorem.cfg` will be loaded (which has to be provided by the user), `[standard]` will load `ntheorem.std`, a predefined setting, and `[noconfig]` does not preload any configuration.

```
443 \gdef\InTheoType{None}
444 \gdef\NoneKeyword{None}
445 \gdef\NoneSymbol{None}
446 \gdef\None{None}
```

Set `\InTheoType` to `none` on the upper document level.

`\newtheoremstyle`   With `\newtheoremstyle`, new theorem-layout styles are defined.

```
447 \gdef\newtheoremstyle#1#2#3{%
448   \expandafter\@ifundefined{th@#1}%
449   {\expandafter\gdef\csname th@#1\endcsname{%
450     \def\@begintheorem####1####2{#2}%
451     \def\@opargbegintheorem####1####2####3{#3}}}%
452   {\PackageError{\basename}{Theorem style #1 already defined}\@eha}}
```

Arguments:
⟨*style*⟩:=`#1`: the name of the theoremstyle to be defined,
⟨*cmd_seq1*⟩:=`#2`: command sequence for setting the header for environment instances with no optional text,
⟨*cmd_seq2*⟩:=`#3`: command sequence for setting the header for environment instances with optional text.
Line 448: if this style is not yet defined, define it.
Line 449: define `\th@`⟨*style*⟩ to be a macro which defines
Line 450: a) the two-argument macro `\@begintheorem#1#2` to be ⟨*cmd_seq1*⟩,
Line 451: b) `\@opargbegintheorem#1#2#3` to be ⟨*cmd_seq2*⟩.

The predefined theorem styles use this command.

`\renewtheoremstyle`

```
453 \gdef\renewtheoremstyle#1#2#3{%
454   \expandafter\@ifundefined{th@#1}%
455   {\PackageError{\basename}{Theorem style #1 undefined}\@ehc}%
456     {}%
457   \expandafter\let\csname th@#1\endcsname\relax
458   \newtheoremstyle{#1}{#2}{#3}}
```

Arguments:
⟨*style*⟩:=`#1`: the name of the theoremstyle to be defined,
`#2`, `#3` as for `\newtheoremstyle`.
Checks, if theoremstyle ⟨*style*⟩ is already defined. If so, `\th@`⟨*style*⟩ is made undefined and `\newtheoremstyle` is called with the same arguments.

Predefined Theorem Styles

theoremstyles   `th@plain`, `th@change`, and `th@margin` taken from theorem.sty by Frank Mittelbach; the break-styles have been changed.

```
459 \newtheoremstyle{plain}%
460   {\item[\hskip\labelsep \theorem@headerfont ##1\ ##2\theorem@separator]}%
```

```
461    {\item[\hskip\labelsep \theorem@headerfont ##1\ ##2\ (##3)\theorem@separator]}
462 %
463 \newtheoremstyle{break}%
464    {\item[\rlap{\vbox{\hbox{\hskip\labelsep \theorem@headerfont
465           ##1\ ##2\theorem@separator}\hbox{\strut}}}]}%
466    {\item[\rlap{\vbox{\hbox{\hskip\labelsep \theorem@headerfont
467           ##1\ ##2\ (##3)\theorem@separator}\hbox{\strut}}}]}
468 %
469 \newtheoremstyle{change}%
470    {\item[\hskip\labelsep \theorem@headerfont ##2\ ##1\theorem@separator]}%
471    {\item[\hskip\labelsep \theorem@headerfont ##2\ ##1\ (##3)\theorem@separator]}
472 %
473 \newtheoremstyle{changebreak}%
474    {\item[\rlap{\vbox{\hbox{\hskip\labelsep \theorem@headerfont
475           ##2\ ##1\theorem@separator}\hbox{\strut}}}]}%
476    {\item[\rlap{\vbox{\hbox{\hskip\labelsep \theorem@headerfont
477           ##2\ ##1\ (##3)\theorem@separator}\hbox{\strut}}}]}
478 %
479 \newtheoremstyle{margin}%
480    {\item[\theorem@headerfont \llap{##2}\hskip\labelsep ##1\theorem@separator]}%
481    {\item[\theorem@headerfont \llap{##2}\hskip\labelsep ##1\ (##3)\theorem@separator]}
482 %
483 \newtheoremstyle{marginbreak}%
484    {\item[\rlap{\vbox{\hbox{\theorem@headerfont
485      \llap{##2}\hskip\labelsep\relax ##1\theorem@separator}\hbox{\strut}}}]}
486    {\item[\rlap{\vbox{\hbox{\theorem@headerfont
487      \llap{##2}\hskip\labelsep\relax ##1\
488      (##3)\theorem@separator}\hbox{\strut}}}]}
489 %
490 \newtheoremstyle{nonumberplain}%
491    {\item[\theorem@headerfont\hskip\labelsep ##1\theorem@separator]}%
492    {\item[\theorem@headerfont\hskip \labelsep ##1\ (##3)\theorem@separator]}
493 %
494 \newtheoremstyle{nonumberbreak}%
495    {\item[\rlap{\vbox{\hbox{\hskip\labelsep \theorem@headerfont
496           ##1\theorem@separator}\hbox{\strut}}}]}%
497    {\item[\rlap{\vbox{\hbox{\hskip\labelsep \theorem@headerfont
498           ##1\ (##3)\theorem@separator}\hbox{\strut}}}]}
499 %
500 \newtheoremstyle{empty}%
501    {\item[]}%
502    {\item[\theorem@headerfont \hskip\labelsep\relax ##3]}
503 \newtheoremstyle{emptybreak}%
504    {\item[]}%
505    {\item[\rlap{\vbox{\hbox{\hskip\labelsep\relax \theorem@headerfont
506           ##3\theorem@separator}\hbox{\strut}}}]}
507 %
508 \@namedef{th@nonumbermargin}{\th@nonumberplain}
509 \@namedef{th@nonumberchange}{\th@nonumberplain}
510 \@namedef{th@nonumbermarginbreak}{\th@nonumberbreak}
511 \@namedef{th@nonumberchangebreak}{\th@nonumberbreak}
512 \@namedef{th@plainNo}{\th@nonumberplain}
513 \@namedef{th@breakNo}{\th@nonumberplain}
514 \@namedef{th@marginNo}{\th@nonumberplain}
```

```
515 \@namedef{th@changeNo}{\th@nonumberplain}
516 \@namedef{th@marginbreakNo}{\th@nonumberbreak}
517 \@namedef{th@changebreakNo}{\th@nonumberbreak}
```

For instance, `break` is commented:
`\newtheoremstyle{break}` results in

```
    \gdef\th@break{%
      \def\@begintheorem##1##2{%
          \item[\hskip\labelsep \theorem@headerfont
                  ##1\ ##2\theorem@separator]%
          \hfill\penalty-8000}%
      \def\@opargbegintheorem##1##2##3{%
        \item[\hskip\labelsep \theorem@headerfont
                ##1\ ##2\ (##3)\theorem@separator]%
        \hfill\penalty-8000}}
```

Then, calling `\th@break` sets `\@begintheorem` as follows:
Since each theorem environment is basically a trivlist, the header is set as the item contents: `\theorem@headerfont` holds the font commands for the header font, `##1` is the keyword to be displayed, and `##2` its environment number. The linebreak after the header is achieved by offering to fill the line with space and the distinct wish to put a linebreak after it. Thus, if plain text follows, the line break is executed, but if a list or a display follows, it is not executed.
Note: The `\hfill\penalty-8000` causes TeX to leave vertical mode, setting the item contents (ie the header) and entering horizontal mode to perform the `\hfill`.

`\theoremstyle` The handling of `\theoremstyle`, `\theorembodyfont`, and `\theoremskipamounts` is taken from theorem.sty by Frank Mittelbach:

```
518 \gdef\theoremstyle#1{%
519    \@ifundefined{th@#1}{\@warning
520            {Unknown theoremstyle '#1'. Using 'plain'}%
521            \theorem@style{plain}}%
522       {\theorem@style{#1}}}
523 \newtoks\theorem@style
524 \newtoks\theorem@@style
525 \global\theorem@style{plain}
```

If `\theoremstyle` is called, it is checked if the argument is a valid `theoremstyle`, and if so, it is stored in the token `\theorem@style`. It is initialized to `plain`.

`\theorembodyfont`

```
526 \newtoks\theorembodyfont
527 \global\theorembodyfont{\itshape}
```

`\theoremnumbering`

```
528 \newtoks\theoremnumbering
529 \global\theoremnumbering{arabic}
```

`\theorempreskipamount`
`\theorempostskipamount`
```
530 \newskip\theorempreskipamount
531 \newskip\theorempostskipamount
532 \global\theorempreskipamount\topsep
533 \global\theorempostskipamount\topsep
```

44

`\theoremindent`

```
534 \newdimen\theoremindent
535 \global\theoremindent0cm
536 \newdimen\theorem@indent
```

`\theoremheaderfont`

```
537 \newtoks\theoremheaderfont
538 \global\theoremheaderfont{\normalfont\bfseries}
539 \def\theorem@headerfont{\normalfont\bfseries}
```

`\theoremseparator`

```
540 \newtoks\theoremseparator
541 \global\theoremseparator{}
542 \def\theorem@separator{}
```

`\theoremprework`
`\theorempostwork`
```
543 \newtoks\theoremprework
544 \global\theoremprework{\relax}
545 \newtoks\theorempostwork
546 \global\theorempostwork{\relax}
547 \def\theorem@prework{}
```

`\theoremsymbol`

```
548 \newtoks\theoremsymbol
549 \global\theoremsymbol{}
```

`\qedsymbol`

```
550 \newtoks\qedsymbol
551 \global\qedsymbol{}
```

`\theoremkeyword`

```
552 \newtoks\theoremkeyword
553 \global\theoremkeyword{None}
```

`\theoremclass`

```
554 \gdef\theoremclass#1{%
555     \csname th@class@#1\endcsname}
556 \gdef\th@class@LaTeX{%
557     \theoremstyle{plain}
558     \theoremheaderfont{\normalfont\bfseries}
559     \theorembodyfont{\itshape}
560     \theoremseparator{}
561     \theoremprework{\relax}
562     \theorempostwork{\relax}
563     \theoremindent0cm
564     \theoremnumbering{arabic}
565     \theoremsymbol{}}
```

Calling `\theoremclass{`⟨*env*⟩`}` calls `\th@class@`⟨*env*⟩ (which is defined in `\@newtheorem` in Lines –45667). `\th@class@`⟨*env*⟩ restores all style parameters to their values given for ⟨*env*⟩. Especially, `\th@class@LaTeX` restores the standard LaTeX parameters.

```
566 \newtoks\qedsymbol
567 \global\qedsymbol{}
```

Compatibility with amsthm.

```

46

Defines theorem styles `plain`, `definition`, and `remark`, and environment `proof` according to `amsthm.sty`.

7.1.7 Theorem-Environment Handling Stuff

Original: ltthm.dtx

```
613 \newskip\thm@topsepadd
```

An auxiliary variable.

Defining New Theorem-Environments.

\newtheorem

```
614 \gdef\newtheorem{%
615   \newtheorem@i%
616 }
```

\newtheorem@i   The syntax of the original `\newtheorem` is retained. The macro is extended to deal with the additional requirements:

```
617 \gdef\newtheorem@i{%
618   \@ifstar
619     {\expandafter\@ifundefined{th@nonumber\the\theorem@style}%
620   {\PackageError{\basename}{Theorem style {nonumber\the\theorem@style}
621         undefined (you need it here for newtheorem*) }\@ehc}%
622     {}%
623   \edef\@tempa{{nonumber\the\theorem@style}}%
624    \expandafter\theorem@@style\@tempa\@newtheorem}%
625   {\edef\@tempa{{\the\theorem@style}}%
626    \expandafter\theorem@@style\@tempa\@newtheorem}}
```

Defines `\theorem@@style` to be the current `\theoremstyle` or – in case of `\newtheorem*` – to be its non-numbered equivalent (which has to be defined!), and then calls `\@newtheorem`.

\renewtheorem

```
627 \gdef\renewtheorem{%
628   \@ifstar
629     {\expandafter\@ifundefined{th@nonumber\the\theorem@style}%
630   {\PackageError{\basename}{Theorem style {nonumber\the\theorem@style}
631         undefined (you need it here for newtheorem*) }\@ehc}%
632     {}%
633   \edef\@tempa{{nonumber\the\theorem@style}}%
634    \expandafter\theorem@@style\@tempa\@renewtheorem}%
635   {\edef\@tempa{{\the\theorem@style}}%
636    \expandafter\theorem@@style\@tempa\@renewtheorem}}
```

Analogous to `\newtheorem`.

\@newtheorem   `\@newtheorem` does the main job for initializing a new theorem environment type. It is called by `\newtheorem`.

```
637 \gdef\@newtheorem#1{%
638   \thm@tempiffalse
639   \expandafter\@ifdefinable\csname #1\endcsname
```

```
640    {\expandafter\@ifdefinable\csname #1*\endcsname
641     {\thm@tempiftrue
642      \thm@definelthm{#1}% for lists
643      \if@thmmarks
644        \expandafter\@ifundefined{c@curr#1ctr}%
645          {\newcounter{curr#1ctr}}{}%
646        \expandafter\@ifundefined{c@end#1ctr}%

680        \noexpand\theoremsymbol{\the\theoremsymbol}}%
681     }}%
682    \theoremprework{\relax}%
683    \theorempostwork{\relax}%
684    \@ifnextchar[{\@othm{#1}}{\@nthm{#1}}}% MUST NOT BE IN ANY IF !!!
```

Argument: $\langle env\rangle$:=#1 is the (internal) environment name to be defined, which is read from the LaTeX source.

Line 639: check if $\langle env\rangle$ is not yet defined (or is redefined).

Lines 641–666 are executed exactly if $\langle env\rangle$ and $\langle env\rangle$* are not yet defined.

Line 641: \thm@tempif=true iff $\langle env\rangle$ and $\langle env\rangle$* are not yet defined.

Line 642: Initialize theorem list handling for $\langle env\rangle$.

Lines 644–647: if thmmarks is active and the counters are not yet defined, for every

theorem-like, define

curr$\langle env\rangle$ctr: in the ith environment of type $\langle env\rangle$, curr$\langle env\rangle$ctr $= i$, and
end$\langle env\rangle$ctr: when the innermost environment is of type $\langle env\rangle$, in the jth
potential position for an end mark in this environment, end$\langle env\rangle$ctr $= j$. (if
the counters are already defined, $\langle env\rangle$ is redefined, and these internal counters
have to be continued).

Lines 649–666: define several commands: (\xdef expands the definition at the time
it is called and makes it global):

Line 649: store the current value of \theoremsymbol (\edef: expand \the\theoremsymbol
now) as $\langle env\rangle$Symbol.

Line 650: store the current value of \theorempostwork (\edef: expand \the\theorempostwork
now) as $\langle env\rangle$postwork.

Lines 651–653, 654–656: Define the commands \env and \env* to set the header of
\env. (using a switch \thm@starredenv: \relax iff starred).

Lines 657, 658: Set \end$\langle env\rangle$* to \end$\langle env\rangle$.

Lines 659–669: define \setparms@$\langle env\rangle$ to set the style parameters of the header
for every $\langle env\rangle$ environment (in the sequel, *current* means, at the moment
\@newtheorem is called):

Lines 660, 661: setting \theorem@headerfont to the *current* value of \theoremheaderfont,
followed by a check if it is a bold style,

Lines 662, 663: setting \theorem@separator to the *current* value of \theoremseparator,

Lines 664, 665: setting \theorem@prework to the *current* value of \theoremprework,

Lines 666, 667: setting \theorem@indent to the *current* value of \theoremindent,

Line 668: executing the command sequence currently stored in \theorembodyfont,
and

Line 669: calling th@\the\theorem@@style (which initializes \@begintheorem and
\@opargbegintheorem according to the *current* value of \theoremstyle by
calling th@\the\theorem@@style).

Line 670–684: define \th@class@$\langle env\rangle$ to initialize all style parameters as they are
set for the $\langle env\rangle$ environment.

Note, that the \@ifdefinable from line 639 ends after line 684.

Line 685: According to the next character, call \@othm{$\langle env\rangle$} (if another counter
is used) or \@nthm{$\langle env\rangle$}.

Thus, when calling \@newthm with #1=$\langle env\rangle$, for current values \theoremstyle=plain,
\theorembodyfont=\upshape, \theoremheaderfont=\bf, \theoremseparator=:,
\theoremindent=1cm, \theoremnumbering=arabic, and \theoremsymbol=\Box,
the macro \setparms@$\langle env\rangle$ is defined as

```
\setparms@⟨env⟩ == \def\theorem@headerfont{\bf\theorem@checkbold}
                   \def\theorem@separator{:}
                   \def\theorem@indent{0cm}
                   \upshape
                   \th@plain
```

and the macro \th@class@$\langle env\rangle$ is defined as

```
\th@class@⟨env⟩ == \def\theoremstyle{plain}
                   \def\theoremheaderfont{\bf}
```

49

```
\def\theorembodyfont{\upshape}
\def\theoremseparator{:}
\def\theoremindent{0cm}
\def\theoremnumbering{arabic}
\def\theoremsymbol{\Box}
```

Note, that line 668 must not be inside *any* `\if...\fi` construct.

\@renewtheorem

```
685 \gdef\@renewtheorem#1{%
686   \expandafter\@ifundefined{#1}%
687   {\PackageError{\basename}{Theorem keyword #1 undefined}\@ehc}%
688      {}%
689   \expandafter\let\csname #1\endcsname\relax
690   \expandafter\let\csname #1*\endcsname\relax
691   \@newtheorem{#1}}
```

Argument: $\langle env\rangle$:=`#1` is the (internal) environment name to be redefined, which is read from the LATEX source.

If $\langle env\rangle$ is already defined, make it (and $\langle env\rangle$*, too) undefined and call `\@newtheorem{`$\langle env\rangle$`}`.

\@nthm   `\@nthm` is called by `\@newtheorem` if the environment to be defined has a counter of its own.

```
692 \gdef\@nthm#1#2{%
693   \expandafter\protected@xdef\csname num@addtheoremline#1\endcsname{%
694            \noexpand\@num@addtheoremline{#1}{#2}}%
695   \expandafter\protected@xdef\csname nonum@addtheoremline#1\endcsname{%
696            \noexpand\@nonum@addtheoremline{#1}{#2}}%
697   \theoremkeyword{#2}%
698   \expandafter\protected@xdef\csname #1Keyword\endcsname
699            {\the\theoremkeyword}%
700   \@ifnextchar[{\@xnthm{#1}{#2}}{\@ynthm{#1}{#2}}}
```

Arguments:

$\langle env\rangle$:=`#1` is the (internal) environment name to be defined (transmitted from `\@newtheorem`).

$\langle output\_name\rangle$:=`#2` is its keyword to be used in the output (read from the LATEX source).

Lines 693–696: Define `\(no)num@addtheoremline`$\langle env\rangle$ to call

    `\@(no)num@addtheoremline{`$\langle env\rangle$`}{`$\langle output\_name\rangle$`}`.

    For comments on `\@num@addtheoremline` and `\@nonum@addtheoremline` see Section 7.1.9.

Lines 697–699: Define `\`$\langle env\rangle$`Keyword`$\langle env\rangle$ to typeset/output $\langle output\_name\rangle$. (note the similarity with the handling of `\theoremsymbol` for handling complex keywords)

Line 700: According to the next character, call `\@xnthm{`$\langle env\rangle$`}{`$\langle output\_name\rangle$`}` (if $\langle env\rangle$-environments should be numbered relative to some structuring level) or `\@ynthm{`$\langle env\rangle$`}{`$\langle output\_name\rangle$`}`.

\@othm   `\@othm` is called by `\@newtheorem` if the environment to be defined uses another counter.

```
701 \gdef\@othm#1[#2]#3{%
```

50

```
702    \@ifundefined{c@#2}{\@nocounterr{#2}}%
703    {\ifthm@tempif
704      \global\@namedef{the#1}{\@nameuse{the#2}}%
705      \expandafter\protected@xdef\csname num@addtheoremline#1\endcsname{%
706              \noexpand\@num@addtheoremline{#1}{#3}}%
707      \expandafter\protected@xdef\csname nonum@addtheoremline#1\endcsname{%
708              \noexpand\@nonum@addtheoremline{#1}{#3}}%
709      \theoremkeyword{#3}%
710      \expandafter\protected@xdef\csname #1Keyword\endcsname
711              {\the\theoremkeyword}%
712      \expandafter\gdef\csname mkheader@#1\endcsname
713        {\csname setparms@#1\endcsname
714                \@thm{#1}{#2}{#3}}%
715      \global\@namedef{end#1}{\@endtheorem}\fi}}
```

Arguments:

⟨*env*⟩:=#1 is the (internal) environment name to be defined (transmitted from \@newtheorem).

⟨*use_ctr*⟩:=#2 is the internal name of the theorem which counter is used, and

⟨*output_name*⟩:=#3 is its "name" to be used in the output (both read from the LaTeX source).

Line 702: if the counter to be used is undefined, goto error, else set \the⟨*env*⟩ to use \the⟨*use_ctr*⟩ and do the following:

Lines 704–712 happen only if ⟨*env*⟩ is not yet defined or gets redefined:

Line 704: (from latex.ltx) make ⟨*env*⟩ use the counter ⟨*use_ctr*⟩.

Lines 705–711 similar to lines 693–699 of \@nthm.

Lines 712–714 define \mkheader@⟨*env*⟩ to set the style parameters of the header and set the header (by \@thm):

$$\mkheader@⟨env⟩ == \setparms@⟨env⟩\@thm\{⟨env⟩\}\{⟨use\_ctr⟩\}\{⟨output\_name⟩\}.$$

(\setparms@⟨*env*⟩ is defined when \@newtheorem{⟨*env*⟩} is carried out).

Line 715: (from latex.ltx): \end⟨*env*⟩ calls \@endtheorem.

\@xnthm   \@xnthm is called by \@nthm if the numbering is relative to some structuring level.

```
716 \gdef\@xnthm#1#2[#3]{%
717    \ifthm@tempif
718      \expandafter\@ifundefined{c@#1}%
719          {\@definecounter{#1}}{}%
720      \@newctr{#1}[#3]%
721      \expandafter\xdef\csname the#1\endcsname{%
722        \expandafter\noexpand\csname the#3\endcsname \@thmcountersep
723          {\noexpand\csname\the\theoremnumbering\endcsname{#1}}}%
724      \expandafter\gdef\csname mkheader@#1\endcsname
725        {\csname setparms@#1\endcsname
726          \@thm{#1}{#1}{#2}}%
727      \global\@namedef{end#1}{\@endtheorem}\fi}
```

Arguments:

⟨*env*⟩:=#1 is the (internal) environment name to be defined (transmitted from \@newtheorem).

⟨*output_name*⟩:=#2 is its keyword to be used in the output,

⟨*level*⟩:=#3 is the structuring level relative to which ⟨*env*⟩ has to be numbered (both read from the LaTeX source).

Lines 718–727 happen only if ⟨*env*⟩ is not yet defined or gets redefined:

Lines 718,719: in not yet defined, define ⟨*env*⟩- counter (otherwise, ⟨*env*⟩ is redefined).

Line 721: (from latex.ltx): define the counter for ⟨*env*⟩ and add ⟨*level*⟩ to its reset-triggers.

Lines 722, 723: define \the⟨*env*⟩ to be the command sequence

\the⟨*level*⟩\@thmcountersep⟨*numbering*⟩{⟨*env*⟩} ,

where ⟨*numbering*⟩ is the value of \theoremnumbering when \@xnthm (and thus, \newtheorem{⟨*env*⟩}) is called.

Lines 724–726: define \mkheader@⟨*env*⟩ to set the style parameters of the header and set the header (by \@thm):

\mkheader@⟨*env*⟩ == \setparms@⟨*env*⟩\@thm{⟨*env*⟩}{⟨*env*⟩}{⟨*output_name*⟩}.

(\setparms@⟨*env*⟩ is defined when \@newtheorem{⟨*env*⟩} is carried out).

Line 727: (from latex.ltx): \end⟨*env*⟩ calls \@endtheorem.

\@ynthm   \@ynthm is called by \@nthm if the counter is not relative to any structuring level.

```
728 \gdef\@ynthm#1#2{%
729   \ifthm@tempif
730     \expandafter\@ifundefined{c@#1}%
731       {\@definecounter{#1}}{}%
732     \expandafter\xdef\csname the#1\endcsname
733       {\noexpand\csname\the\theoremnumbering\endcsname{#1}}%
734     \expandafter\gdef\csname mkheader@#1\endcsname
735      {\csname setparms@#1\endcsname
736       \@thm{#1}{#1}{#2}}%
737     \global\@namedef{end#1}{\@endtheorem}\fi}
```

Arguments:

⟨*env*⟩:=#1 is the (internal) environment name to be defined (transmitted from \@newtheorem).

⟨*output_name*⟩:=#2 is its keyword to be used in the output.

\@ynthm works analogous to \@xnthm.

Handling Instances of Theorem-Environments.

\@thm   \@thm is called by \@⟨*env*⟩ (which is defined by \@othm/\@xnthm/\@ynthm).

```
738 \gdef\@thm#1#2#3{%
739   \if@thmmarks
740     \stepcounter{end\InTheoType ctr}%
741   \fi
742   \renewcommand{\InTheoType}{#1}%
743   \if@thmmarks
744     \stepcounter{curr#1ctr}%
745     \setcounter{end#1ctr}{0}%
746   \fi
747   \refstepcounter{#2}%
748   \theorem@prework
749   \thm@topsepadd \theorempostskipamount   % cf. latex.ltx: \@trivlist
```

```
750    \ifvmode \advance\thm@topsepadd\partopsep\fi
751    \trivlist
752    \@topsep \theorempreskipamount
753    \@topsepadd \thm@topsepadd          % used by \@endparenv
754    \advance\linewidth -\theorem@indent
755    \advance\@totalleftmargin \theorem@indent
756    \parshape \@ne \@totalleftmargin \linewidth
757    \@ifnextchar[{\@ythm{#1}{#2}{#3}}{\@xthm{#1}{#2}{#3}}}
```

Changed to three instead of two parameters (the first one is new):

$\langle env \rangle$:=#1: (added) internal name of the theorem environment,

$\langle use\_ctr \rangle$:=#2: internal name of the theorem which counter is used,

$\langle output\_name \rangle$:=#3: keyword to be displayed in the output; all arguments are transmitted from \@othm/\@xnthm/\@ynthm.

Lines 739–741: if thmmarks is active, the counter for the current environment $\langle env' \rangle$ is incremented, since the last endmark in environment $\langle env' \rangle$ is definitely not the position for its endmark (necessary for nested environments ending at the same time).

Line 742: set \InTheoType to $\langle env \rangle$.

Lines 743–746: if thmmarks is active, increment curr$\langle env \rangle$ctr and set end$\langle env \rangle$ctr to 0.

Line 747: adapted from latex.ltx: increment the corresponding counter.

Line 748: perform prework (before theorem structure is generated).

Lines 749–753: handle \theorempreskipamount and \theorempostskipamount (if in vmode, there is additional space, cf. \trivlist and \@trivlist in latex.ltx).

Lines 754–756: handle \theoremindent.

Line 757: if there is an optional argument, call \@ythm{$\langle env \rangle$}{$\langle use\_ctr \rangle$}{$\langle output\_name \rangle$}, otherwise call \@xthm{$\langle env \rangle$}{$\langle use\_ctr \rangle$}{$\langle output\_name \rangle$}.

\@xthm   \@xthm is called by \@thm if there is no optional text in the theorem header.

```
758 \def\@xthm#1#2#3{%
759    \@begintheorem{#3}{\csname the#2\endcsname}%
760    \ifx\thm@starredenv\@undefined
761      \thm@thmcaption{#1}{{#3}{\csname the#2\endcsname}{}}\fi
762    \ignorespaces}
```

Changed to three instead of two parameters (the first one is new):

$\langle env \rangle$:=#1: (added) internal name of the theorem environment,

$\langle use\_ctr \rangle$:=#2: internal name of the theorem which counter is used,

$\langle output\_name \rangle$:=#3: keyword to be displayed in the output.

All arguments are transmitted from \@thm.

For comments, see \@ythm.

\@ythm   \@ythm is called by \@thm if there is an optional text in the theorem header.

```
763 \def\@ythm#1#2#3[#4]{%
764    \expandafter\global\expandafter\def\csname#1name\endcsname{#4}%
765    \@opargbegintheorem{#3}{\csname the#2\endcsname}{#4}%
766    \ifx\thm@starredenv\@undefined
767      \thm@thmcaption{#1}{{#3}{\csname the#2\endcsname}{#4}}\fi%
768    \ignorespaces}
```

Changed to four instead of three parameters (the first one is new):

⟨*env*⟩:=#1: (added) internal name of the theorem environment,

⟨*use_ctr*⟩:=#2: internal name of the theorem which counter is used,

⟨*output_name*⟩:=#3: keyword to be displayed in the output.

⟨*opt_text*⟩:=#4: optional text to appear in the header.

#1–#3 are transmitted from `\@thm`, #4 is read from the LaTeX source.

Line 764: define `\⟨env⟩name` to be the optional argument.

Line 765: call

$$\text{\textbackslash @opargbegintheorem\{}⟨output\_name⟩\}\{\text{\textbackslash the}⟨use\_ctr⟩\}\{⟨opt\_text⟩\}$$

which outputs the header.

Line 766, 767: if ⟨*env*⟩ is not the starred version, call

$$\text{\textbackslash thm@thmcaption\{}⟨env⟩\}\{\{⟨output\_name⟩\}\{\text{\textbackslash the}⟨use\_ctr⟩\}\{⟨opt\_text⟩\}\}$$

which makes an entry into the theorem list.

`\@endtheorem` `\@endtheorem` is called for every `\end{⟨env⟩}`, where ⟨*env*⟩ is a theorem-like environment. (note that `\@endtheorem` it is also changed by option [thmmarks] to organize the placement of the corresponding end mark). `\InTheoType` gives the innermost theorem-like environment, i.e. the one to be ended:

```
769 \gdef\@endtheorem{%
770   \endtrivlist
771   \csname\InTheoType @postwork\endcsname
772   }
```

7.1.8 Framed and Boxed Theorems

The option 'framed' activates framed and boxed layouts. It requires to load the `framed` package and the `pstricks` package.

framed

```
773 \DeclareOption{framed}{%******************************
774 \newtoks\shadecolor
775 \shadecolor{gray}
776 \let\theoremframecommand\relax
```

newshadedtheorem

```
777 \def\newshadedtheorem#1{%
778   \expandafter\global\expandafter\xdef\csname#1@shadecolor\endcsname{%
779     \the\shadecolor}%
780   \ifx\theoremframecommand\relax
781     \expandafter\global\expandafter\xdef\csname#1@framecommand\endcsname{%
782       \noexpand\psframebox[fillstyle=solid,
783                 fillcolor=\csname#1@shadecolor\endcsname,
784                 linecolor=\csname#1@shadecolor\endcsname]}%

798    }
799 }% end of option framed **********************************************
```

7.1.9 Generation of Theorem Lists

The following macros are are needed for the generation of theorem-lists. We will document it for the theorem `\begin{definition}[optional]`, which we assume to be the first definition at all and which is placed on page 5.

`\thm@thmcaption` This macro, used internally, strips of the outer brackets from the second argument and calls `\thm@@thmcaption`. It's typically called like this

   `\thm@thmcaption{definition}{{Definition}{1}{optional}}`

(internal name of the environment, output keyword, running number, optional text)

```
800 \def\thm@thmcaption#1#2{\thm@@thmcaption{#1}#2}
```

`\thm@@thmcaption` `\thm@caption` is called from `\thm@caption`; it writes an appropriate entry to the `.thm`-file.

```
801 \def\thm@@thmcaption#1#2#3#4{%
802     \thm@parseforwriting{#2}%
803     \let\thm@tmpii\thm@tmp%
804     \thm@parseforwriting{#4}%
805     \edef\thm@t{{\thm@tmpii}{#3}{\thm@tmp}}%
806     \addcontentsline{thm}{#1}{\thm@t}}
```

Arguments: ⟨*env*⟩:=`#1` is the internal environment name, ⟨*output_name*⟩:=`#2` is its keyword to be used in the output, `#3` is the running number, and `#4` is the optional text argument in the header.

Lines 801,802: the command sequence for the output keyword is prepared by `\thm@parseforwriting` (which returns `\thm@tmpii`) and then stored in `\thm@tmpii`.

Line 803: the optional text is also prepared by `\thm@parseforwriting`

Lines 804,805: The output is collected and written into the `.aux` file, which will forward it to the theorem-file.

The following two macros are just shortcuts, often needed for the output of one single line in the theorem-lists. The first one is used in unnamed lists, the second one in named. Warning: Don't remove the leading `\let`, since you will get wrong `\if`-`\fi`-nesting without it, if you don't use `hyperref`.

`\thm@@thmline@noname`

```
807 \def\thm@@thmline@noname#1#2#3#4{%
808             \@dottedtocline{-2}{0em}{2.3em}%
809                     {\protect\numberline{#2}#3}%
810                     {#4}}
```

`\thm@@thmline@name`

```
811 \def\thm@@thmline@name#1#2#3#4{%
812        \@dottedtocline{-2}{0em}{2.3em}%
813                  {#1 \protect\numberline{#2}#3}%
814                  {#4}}
```

`\thm@thmline` This is another short one, which only discards the outer brackets from the first argument and calls `\thm@@thmline`. It's normally called like this:

`\thm@@thmline{{Definition}{1}{optional}}{5}`

```
815 \def\thm@thmline#1#2{\thm@@thmline#1{#2}}
```

`\thm@lgobble` The next macro is used to ignore all theorem-sets, which should not be listed.

```
816 \long\def\thm@lgobble#1#2{\ignorespaces}
```

The following four macros set up the predefined list-types. To do so, they define the internal macros `\thm@@thmlstart` (containing the code to be executed at the beginning of the list), `\thm@@thmlend` (code to be executed at the end of the list) and `\thm@@thmline` (code to be executed for every line). In order to gain compatibility with `newthm.sty`, we decided not to make this commands inaccessible to the user. But we recommend not using these commands, because they may disappear in later distributions.

`\theoremlistall` This one implements the type `all`.

```
817 \def\theoremlistall{%
818      \let\thm@@thmlstart=\relax
819      \let\thm@@thmlend=\relax
820      \let\thm@@thmline=\thm@@thmline@noname}
```

`\theoremlistallname` And here's the type `allname`.

```
821 \def\theoremlistallname{%
822      \let\thm@@thmlstart=\relax
823      \let\thm@@thmlend=\relax
824      \let\thm@@thmline=\thm@@thmline@name}
```

`\theoremlistoptional` This one is the list-type `opt`. In case of [`hyperref`], the fifth argument, which is provided by `hyperref.sty` is automatically given to `\thm@@thmline@noname`.

```
825 \def\theoremlistoptional{%
826      \let\thm@@thmlstart=\relax
827      \let\thm@@thmlend=\relax
828      \def\thm@@thmline##1##2##3##4{%
829          \ifx\empty ##3%
830          \else
831              \thm@@thmline@noname{##1}{##2}{##3}{##4}%
832          \fi}}
```

`\theoremlistoptname` And the last type, `optname`. In case of [`hyperref`], the fifth argument, which is provided by `hyperref.sty` is automatically given to `\thm@@thmline@name`.

```
833 \def\theoremlistoptname{%
834      \let\thm@@thmlstart=\relax
835      \let\thm@@thmlend=\relax
836      \def\thm@@thmline##1##2##3##4{%
```

```
837          \ifx\empty ##3%
838          \else%
839              \thm@@thmline@name{##1}{##2}{##3}{##4}%
840          \fi}}
```

Theoremlists and Hyperref   Since the `hyperref`-package redefines `\contentsline`, we must redefine some commands to handle this:

1. Let the different versions of `\thm@@thmline@..` take a 5th argument, the one provided by `hyperref`.

2. Don't use hyperref's contentsline: restore the normal definition at the beginning of `\thm@processlist` (see there).

3. Let `\thm@lgobble` take one more argument, the one provided by hyperref.

4. Do the hyperlinks manually in the different versions of `\thm@@thmline` as defined by the theoremtypes.

hyperref

```
841 \DeclareOption{hyperref}{% ********************************************
842     \def\thm@@thmline@noname#1#2#3#4#5{%
843         \ifx\\#5\\%
844             \@dottedtocline{-2}{0em}{2.3em}%
845                 {\protect\numberline{#2}#3}%
846                 {#4}%
847         \else
848             \ifHy@linktocpage\relax\relax
849                 \@dottedtocline{-2}{0em}{2.3em}%
850                     {\protect\numberline{#2}#3}%
851                     {\hyper@linkstart{link}{#5}{#4}\hyper@linkend}
852             \else
853                 \@dottedtocline{-2}{0em}{2.3em}%
854                     {\hyper@linkstart{link}{#5}{\protect\numberline{#2}#3}%
855                      \hyper@linkend}%
856                     {#4}%
857             \fi
858         \fi}%
859     \def\thm@@thmline@name#1#2#3#4#5{%
860         \ifx\\#5\\%
861             \@dottedtocline{-2}{0em}{2.3em}%
862                 {#1 \protect\numberline{#2}#3}%
863                 {#4}
864         \else
865             \ifHy@linktocpage\relax\relax
866                 \@dottedtocline{-2}{0em}{2.3em}%
867                     {#1 \protect\numberline{#2}#3}%
868                     {\hyper@linkstart{link}{#5}{#4}\hyper@linkend}%
869             \else
870                 \@dottedtocline{-2}{0em}{2.3em}%
871                     {\hyper@linkstart{link}{#5}%
872                      {#1 \protect\numberline{#2}#3}\hyper@linkend}%
873                     {#4}%
```

```
874              \fi
875            \fi}
876        \def\thm@thmline#1#2#3{\thm@@thmline#1{#2}{#3}}
877        \long\def\thm@lgobble#1#2#3{\ignorespaces}
878        \def\theoremlistoptional{%
879            \let\thm@@thmlstart=\relax
880            \let\thm@@thmlend=\relax
881            \def\thm@@thmline##1##2##3##4##5{%
882                \ifx\empty ##3%
883                \else%
884                    \thm@@thmline@noname{##1}{##2}{##3}{##4}{##5}%
885                \fi}}
886        \def\theoremlistoptname{%
887            \let\thm@@thmlstart=\relax
888            \let\thm@@thmlend=\relax
889            \def\thm@@thmline##1##2##3##4##5{%
890                \ifx\empty ##3%
891                \else%
892                    \thm@@thmline@name{##1}{##2}{##3}{##4}{##5}%
893                \fi}}
894 }% end of option hyperref *******************************************
```

\theoremlisttype The next one is the user-interface for selecting the list-type. It simply calls \thm@thml@⟨*type*⟩, if the given ⟨*type*⟩ is defined.

```
895 \def\theoremlisttype#1{%
896     \@ifundefined{thm@thml@#1}%
897         {\PackageError{\basename}{Listtype #1 not defined}\@eha}%
898         {\csname thm@thml@#1\endcsname}}
```

Now, here is a the code, which maps the types – selected by \theoremlisttype – to the defined macros.

```
899 \def\thm@thml@all{\theoremlistall}
900 \def\thm@thml@opt{\theoremlistoptional}
901 \def\thm@thml@optname{\theoremlistoptname}
902 \def\thm@thml@allname{\theoremlistallname}
```

\newtheoremlisttype According to the given documentation, this one can be used to define new list-types. It's done by defininig the macro \thm@thml@⟨*type*⟩, which *locally* redefines the commands \thm@thmlstart, \thm@@thmline and \thm@@thmlend.

```
903 \def\newtheoremlisttype#1#2#3#4{%
904   \@ifundefined{thm@thml@#1}%
905   {\expandafter\gdef\csname thm@thml@#1\endcsname{%
906     \def\thm@@thmlstart{#2}%
907     \def\thm@@thmline####1####2####3####4{#3}%
908     \def\thm@@thmlend{#4}}%
909   }{\PackageError{\basename}{list type #1 already defined}\@eha}}
```

\renewtheoremlisttype

```
910 \def\renewtheoremlisttype#1#2#3#4{%
911   \@ifundefined{thm@thml@#1}%
912     {\PackageError{\basename}{List type #1 not defined}\@ehc}{}%
913   \expandafter\let\csname thm@thml@#1\endcsname\relax
914   \newtheoremlisttype{#1}{#2}{#3}{#4}}
```

58

if the list type to be redefined is already defined, make it undefined and define it.

\thm@definelthm For each theorem-set, we need to setup two commands. Thus, the next macro is called by \newtheorem. It defines the command \l@⟨theorem-set⟩ and \thm@listdo⟨theorem-set⟩, which initially discard the input by calling \thm@lgobble. The first one is called for each theorem when you are generating lists. The second one is called, if you've added something with \addtotheoremfile.

```
915 \def\thm@definelthm#1{%
916 \expandafter\gdef\csname l@#1\endcsname{\thm@lgobble}%
917 \expandafter\gdef\csname thm@listdo#1\endcsname{\thm@lgobble}}
```

\thm@inlistdo If in some case, you've written additional text into the theorem-file by \addtotheoremfile, this one is called internally. It simply discards the first argument and strips of the outer brackets from the second one.

```
918 \long\def\thm@inlistdo#1#2{#2}%
```

\listtheorems Now we need the user-interface for generating lists. This is done by the next macro. We set the tocdepth to -2 to assure that the predefined list-types work. After storing the names of the theorem-sets, we call \thm@processlist, which actually generates the list.

```
919 \def\listtheorems#1{\begingroup
920 \c@tocdepth=-2%
921 \def\thm@list{#1}\thm@processlist
922 \endgroup}
```

\thm@processlist The file ⟨jobname⟩.thm contains commands of the form
      \contentsline{⟨theoremset⟩}{{⟨header⟩}{⟨number⟩}}{⟨page⟩}.
Thus, dependent on which theoremsets should be listed, \contentsline must be defined to evaluate the first argument and then to output all arguments, or to discard the second and third one.

This is done the following way: The commands \l@⟨theorem-set⟩ and \thm@listdo⟨theorem-set⟩ (which initially were set to ignore everything by \newtheorem) are redefined for the theorem sets which should be listed to generate output. \contentsline is defined to call \l@⟨theorem-set⟩, adding a line to the list or ignoring the entry. Since for theorem sets which are not yet known (i.e., if the list is created at the beginning of the document, and the theoremset is only defined later), \l@⟨theorem-set⟩ is not yet defined, \contentsline has to check if the command is defined, otherwise ignore the arguments.

Then, the .thm file is processed, evaluating the \contentsline commands. After processing the theorem-file, the mentioned commands are again redefined to discard everything. We need to define the macros globally for dealing with complex, user-defined, list-types.

```
923 \def\thm@processlist{%
924 \begingroup
925 \typeout{** Generating table of \thm@list}%
926 \def\contentsline##1{%
927     \expandafter\@ifundefined{l@##1}{\thm@lgobble}{\csname l@##1\endcsname}}%
928 \thm@@thmlstart
929 \@for\thm@currentlist:=\thm@list\do{%
930  \ifx\thm@currentlist\@empty\else
931   \expandafter\gdef\csname l@\thm@currentlist\endcsname{\thm@thmline}%
```

```
932    \expandafter\gdef\csname thm@listdo\thm@currentlist\endcsname{\thm@inlistdo}%
933    \fi
934 }%
935 \@input{\jobname .thm}%
936 \thm@@thmlend
937 \@for\thm@currentlist:=\thm@list\do{%
938   \ifx\thm@currentlist\@empty\else
939     \expandafter\gdef\csname l@\thm@currentlist\endcsname{\thm@lgobble}%
940     \expandafter\gdef\csname thm@listdo\thm@currentlist\endcsname{\thm@lgobble}%
941   \fi
942 }%
943 \endgroup}
```

\thm@enablelistoftheorems   Up to now, we've set up various macros for writing and reading the theorem-file.
Thus, it's time to set up the file itself. This is done by the next macro. We simply
took the lines for \@starttoc from the LaTeX-base and changed some things. The
main intention to copy \@starttoc is that we don't want the file to be input when
it is set up – like it's done by \@starttoc.

```
944 \def\thm@enablelistoftheorems{%
945   \begingroup
946     \makeatletter
947     \if@filesw
948       \expandafter\newwrite\csname tf@thm\endcsname%
949       \immediate\openout \csname tf@thm\endcsname \jobname.thm\relax%
950     \fi
951     \@nobreakfalse
952   \endgroup}
```

\addtheoremline   By \addtheoremline{⟨theorem-set⟩}{⟨entry⟩}, the user can insert an extra entry
into the theorem-file. \addtheoremline* calls the internal macro \nonum@addtheoremline,
otherwise \num@addtheoremline is called. \num/nonum@addtheoremline{⟨theorem-set⟩}{⟨entry⟩}
calls \num/nonum@addtheoremline⟨theorem-set⟩{⟨entry⟩} which are defined when
⟨theorem-set⟩ is declared (cf. \@nthm). These in turn call \@num/nonum@addtheoremline{⟨theorem-set⟩
}{⟨keyword⟩}{⟨entry⟩} which write information to the theorem file.

```
953 \def\addtheoremline{\@ifstar{\nonum@addtheoremline}{\num@addtheoremline}}
954 \def\nonum@addtheoremline#1{\csname nonum@addtheoremline#1\endcsname}%
955 \def\num@addtheoremline#1{\csname num@addtheoremline#1\endcsname}%
```

\@nonum@addtheoremline   \@num@addtheoremline and \@nonum@addtheoremline write the actual entries to
the .thm file.
Syntax: \@num/nonum@addtheoremline{ ⟨theorem-set⟩}{⟨keyword⟩}{⟨entry⟩}

```
956 \def\@nonum@addtheoremline#1#2#3{%
957    \thm@parseforwriting{#3}%
958    \edef\thm@t{{#2}{}{\thm@tmp}}%
959    \addcontentsline{thm}{#1}{\thm@t}}
```

\@num@addtheoremline

```
960 \def\@num@addtheoremline#1#2#3{%
961    \thm@parseforwriting{#3}%
962    \edef\thm@t{{#2}{\csname the#1\endcsname}{\thm@tmp}}%
963    \addcontentsline{thm}{#1}{\thm@t}}%
```

\addtotheoremfile To write any additional stuff into the theorem-file, the next macro is used. It first checks, if the optional name of a theorem-set is given. In that case, the macro `\@@addtotheoremfile`, otherwise `\@addtotheoremfile` is used to write the stuff into the file.

```
964 \long\def\addtotheoremfile{%
965     \@ifnextchar[{\@@addtotheoremfile}{\@addtotheoremfile}}
```

\@addtotheoremfile Write additional stuff for all theorems.

```
966 \long\def\@addtotheoremfile#1{%
967     \thm@parseforwriting{#1}%
968     \protected@write\@auxout%
969         {}{\string\@writefile{thm}{\thm@tmp}}}
```

\@@addtotheoremfile Write additional stuff for a given theorem-set.

```
970 \long\def\@@addtotheoremfile[#1]#2{%
971     \thm@parseforwriting{#2}%
972     \protected@write\@auxout%
973         {}{\string\@writefile{thm}{\string\theoremlistdo{#1}{\thm@tmp}}}}
```

\theoremlistdo This one is called from the theorem-file to insert the additional stuff for a theorem-set.

```
974 \long\def\theoremlistdo#1#2{\expandafter\@ifundefined{thm@listdo#1}%
975     \relax{\csname thm@listdo#1\endcsname{#1}{#2}}}
```

Now we assure, that the theorem-file is activated. This is done by inserting a hook at the end of the document.

```
976 \AtEndDocument{\thm@enablelistoftheorems}
```

7.1.10 Auxiliary macros

For generating theorem-lists, we need to write informations into a separate file. Beause we don't want to expand this information, we parse it specially for writing.

```
977 \def\thm@meaning#1->#2\relax{#2}% remove "macro: ->"
978 \long\def\thm@parseforwriting#1{%
979     \def\thm@tmp{#1}%
980     \edef\thm@tmp{\expandafter\thm@meaning\meaning\thm@tmp\relax}}
```

In some countries it's usual to number theorems with greek letters:

\theorem@checkbold For correctness, we need to check if a bold font is active. This is done by the following macro:

```
981 \def\theorem@checkbold{\if b\expandafter\@car\f@series\@nil\boldmath\fi}
```

\@greek Accoding to LATEX-base, this is the internal command for generating lowercase greek numberings.

```
982 \def\@greek#1{\theorem@checkbold%
983 \ifcase#1\or$\alpha$\or$\beta$\or$\gamma$\or$\delta$\or$\varepsilon$%
984     \or$\zeta$\or$\eta$\or$\vartheta$\or$\iota$\or$\kappa$\or$\lambda$\or$%
985     \mu$\or$\nu$\or$\xi$\or$ o$\or$\varpi$\or$\varrho$\or$\varsigma$\or$\tau$%
986     \or$\upsilon$\or$\varphi$\or$\chi$\or$\psi$\or$\omega$\else\@ctrerr\fi}
```

`\@Greek` According to LaTeX-base, this is the internal command for generating uppercase greek numberings.

```
987 \def\@Greek#1{\theorem@checkbold%
988 \ifcase#1\or A\or B\or$\Gamma$\or$\Delta$\or E%
989  \or Z\or H\or$\Theta$\or I\or K\or$\Lambda$\or M%
990  \or N\or$\Xi$\or O\or$\Pi$\or P\or$\Sigma$\or T%
991  \or$\Upsilon$\or$\Phi$\or X\or$\Psi$\or$\Omega$\else\@ctrerr\fi}
```

`\greek` According to LaTeX-base, this is the user interface for lowercase greek numberings.

```
992 \def\greek#1{\@greek{\csname c@#1\endcsname}}
```

`\Greek` According to LaTeX-base, this is the user interface for uppercase greek numberings.

```
993 \def\Greek#1{\@Greek{\csname c@#1\endcsname}}
```

7.1.11 Other Things

After declaring several package-options, we need to process the specified ones. The additional `\relax` was mentioned by Rainer Schöpf at DANTE'97.

```
994 \ProcessOptions\relax
```

Now we set up the default theorem listtype. Make sure this is called after processing the options. Otherwise, ntheorem will break with hyperref.

```
995 \theoremlistall
```

If automatical configuration is not disabled by [noconfig], it is checked if the file `ntheorem.cfg` exists and in this case the definitions in this file are read. If it does not exist and the option `standard` was specified, the file `ntheorem.std` is used.

```
996 \ifx\thm@noconfig\@undefined
997 \InputIfFileExists{ntheorem.cfg}%
998  {\PackageInfo{\basename}{Local config file ntheorem.cfg used}}%
999  {\ifx\thm@usestd\@undefined%
1000   \else%
1001    \InputIfFileExists{ntheorem.std}%
1002     {\PackageInfo{\basename}{Standard config file ntheorem.std used}}{}
1003  \fi}
1004 \fi
```

7.2 The Standard Configuration

```

8 History and Acknowledgements

8.1 The endmark-Story (Wolfgang May)

In 1995, I started a hack for setting endmarks semiautomatically at the end of displayed formulas. The work on `thmmarks.sty` begun in October 1996 by a thread asking for a routine for setting endmarks in *de.comp.tex* initiated by Boris Piwinger. Version 0.1 incorporated the main features for setting endmarks automagically by using the `.aux` file. Version 0.2 included some bugfixes and was the first one accessible on the internet. Boris suggested to include `fleqn` and `leqno` which has been done in version 0.3 (which was never made public). Since at this point, `thmmarks.sty` was incompatible to the widely used `theorem.sty` written by Frank Mittelbach, in Version 0.4, the features of theorem.sty have been integrated.
With version 0.5, the case of "empty" end symbols has been handled, `\qed` has been added (also suggested by Boris), and the handling of theoremstyles by `\newtheoremstyle` has been included.
For version 0.6, the handling of endmarks in displaymaths has been changed in order to adjust them with the bottom of the displayed math.
Version 0.6 was the first one announced in *comp.text.tex*. For version 0.7, I added the handling of `amsmath` features, suggested by my colleague Peter Neuhaus.
Versions 0.71 and 0.72 incorporated minor bugfixes.

8.2 Lists, Lists, Lists (Andreas Schedler)

I often saw questions on theoremlists in the german newsgroup *de.comp.text.tex*, but I never spent any attention on those postings. This changed in summer 1996, when I needed those lists for myself. Thus, I asked the holy question. But none of the given answers satisfied my wish for a simple, easy to use and short solution.

I decided to take a look at Frank Mittelbachs `theorem.sty`. First I didn't understand much of the code, but Bernd Raichle helped me a lot by answering my boring questions and I finally understood it.

I started the coding and within a few days, a first experimental version was born. Not only that I had implemented the lists, I also inserted a separator and a flexible numbering of the theorems.

After a long period of testing, I wanted to share the new features with other TEX-Freaks and wrote an article for the "Die TEXnische Komödie" (Journal of german tug, DANTE e.V.). As soon as I had sent the article to DANTE, I got first reactions on the style. Gerd Neugebauer gave me many hints. I hided several cryptical notations in easy definitions and improved the user interface.

In January 1997, I released "newthm" to the world and it was uploaded to the CTAN-Archives. Few days later I sent my files to Frank Mittelbach in order to show him my extensions. He told me, that already other extensions were made, and that it would be good to combine alltogether.

8.3 Let's come together

With version 0.8, in February 1997, the combination of `thmmarks.sty` with `newthm.sty` to `ntheorem.sty` has been started. On April 21, 1997, version 0.94 beta has been made public as version 1.0.

In course of the development, the following changes were made:

65

8.4 Acknowledgements

This place is dedicated to all those, who helped us developing our separate styles and this combined package. Thanks to (listed in alphabetical order):

Donald Arseneau, Giovanni Dore, Oliver Karch, Frank Mittelbach, Gerd Neugebauer, Heiko Oberdiek, Boris Piwinger, Bernd Raichle, Rainer Schöpf, Didier Verna.
